Fifth Edition 1925
Sixth Edition 1931
Reprinted 1948

PREFACE

I N this edition the work is completely revised, and as far an possible brought up to date. The most noteworthy new seature is the incorporation of all the parts into one general dictionary, and the omission of Part I of previous editions. When first written this had certain advantages, as being one of the few presentations in English of the elementary facts and theories of ecology. But this advantage has long disappeared, and it seemed to me that the space would be better employed in increasing the number of genera dealt with. On consulting Sir David Prain and other botanists. I found that they agreed with this idea. By a slight addition to the total number of pages I have found it possible to include all the genera, and hope that in this way the usefulness of the work to botanists in general may be gre tly increased. I have of course attempted no criticism of those included, but have tried to indicate, as far as space would permit, the genera from which they have been segregated'n many cases, or to which they are united by the other of the two chief recent editors of the vegetable kingdom (Bentham-Hooker, Engler-Prantl). It is obviously impossible to do very much in this direction. As it stands, the book is convenient for use, but a very slight addition to the facts given for each genus would add a line to the entry and, as there are roughly some 20,000 entries, this would add 400 pages to the book, and make it unwieldy. The same remark applies to the geographical distribution. which could not in general be given in great detail.

Before criticising, again, the inclusion of many obsolete technical terms and synonyms, it must be remembered that some who use this book wish to use it in connection with floras now long published, and also that it is impossible to reset such a book all through for each edition, so that it is necessary to insert a little "padding" on practically every page.

A book like this must obviously be a compilation, and I have to express my warmest thanks to Prof. A. Engler for permission to draw upon the vast mass of material contained in *Die Natürlichen Pflanzenfamilien*. Owing to the war I have had no opportunity of asking him to renew this permission, and I trust that he will understand as much. When an article, as is frequently the case with the grouping of the subfamilies within the family, is taken from the work mentioned, I have acknowledged the same by giving the name of the author. Otherwise I have in general drawn upon the book for the genera accepted by its authors, for the number of species (which has been brought roughly up to date by aid of the Supplements to the *Index Kewensis*), and for their geographical distribution.

The list of friends to whom I owe valuable suggestions, useful pieces of assistance, and the like, is very long, and I have no doubt that the following enumeration is incomplete, and must ask the pardon of those who do not figure in it. through some oversight on my part to note down their names at the moment the help was given. In the first place I wish to thank Sir David Prain and the staff at Kew, more especially Drs Hill, Stapf, and Rolfe, and Mr S. A. Skan, whose detailed knowledge of the library has been of the very greatest assistance in easing my labour. The writing of this edition has occupied very much time during the last five years, and I am particularly grateful to Prof. Seward, who placed at my disposal a table large enough to enable me to spread out 20 works of reference at once, and to Dr Moss and others of the Cambridge staff. The first two of the five years were spent in Rio de Janeiro and I am much indebted for help to my colleagues there, particularly the late Dr Alberto

Löfgren and Dr Achilles de Faria Lisbôa. I also owe many useful suggestions to my colleagues in other Botanic Gardens, e.g. Prof. O. Ames at Harvard, Prof. I. B. Balfour at Edinburgh, Prof. N. L. Britton at New York, Mr I. H. Burkill at Singapore, Prof. A. Engler at Berlin, Dr J. H. Maiden at Sydney, the late Dr H. H. W. Pearson at Cape Town, Dr Sargant at Jamaica Plain, and others. The late Dr E. A. N. Arber, and Mrs Arber, have laid me under very many obligations, and so have Sir Francis Darwin, Professors Bower, Farmer, Goebel, Goodale, Henry, Lang, Oliver, Scott, and Yapp, and Messrs Davie, Lock, Lynch, Riddle, Small, Smith, and many more. To my wife my obligations are unmeasured. Finally for the illustrations I have to thank Herr Engelmann for permission to copy some of the late Prof. Eichler's figures. and Dr Rendle for the use of some of those in his book on Classification.

J. C. WILLIS

CAMBRIDGE,
April 4, 1919.

PREFACE TO FIFTH EDITION

Pages 30, 31, 46, 51, 76, 80, 87, 94, 109, 117, 119, 147, 163, 176, 179, 205, 215, 217, 222, 243, 249, 250, 253, 255, 272, 284, 314, 335, 350, 360, 371, 374, 375, 377, 392, 404, 405, 417-20, 439-41, 457, 464, 480, 505, 535, 538, 615, 646 have been rewritten in a style that will gradually be adopted throughout

J. C. W.

March 24, 1925.

PREFACE TO SIXTH EDITION

A considerable number of pages have been completely rewritten in this as in the Fifth Edition.

I. C. W.

January 1931.

INDEX

TO THE IMPORTANT GENERAL ARTICLES, UNDER WHICH LISTS OF EXAMPLES (DESCRIBED AT GREATER LENGTH) WILL BE FOUND.

GENERAL

Abbreviations, Collecting, Concrescence, Description, Dimorphism, Literature, Nomenclature.

VEGETATIVE ORGANS

Adnate, Adventitious, Aerenchyma, Aerial Root, Branch, Bud, Bulb, Bulbil, Cauli(flory), Concrescence, Corm, Iso-(bilateral, &c.), Leaf, Phyllo-(taxy, &c.), Poly-(morphism), Rhizome, Stem, Stipule, Sym-(podium), Thorn, Tuber, Vegetative Reproduction.

REPRODUCTIVE ORGANS

Aestivation, Aggregate fruit, Andro-(phore, &c.), Anemo-(philous), Aniso-(phylly), Apetalous, Apo-(gamy), Aril, Asymmetrical, Bee-flowers, Berry, Bract, Butterfly-flowers, Carrion-flowers, Cincinnus, Cleistogamy, Cyme, Dichasial cyme, Dichogamy, Dioecism, Dispersal, Endo-(sperm, &c.), Epi-(gynous, &c.), Floral, Flower, Fly-flowers, Fruit, Geo-(carpic), Gyno-(dioecism, &c.), Heter-(ostylism), Inflorescence, Loose-pollen mechanisms, Mixed inflorescence, Nectary, Nut, Ovary, Perianth, Pollination, Receptacle, Seed, Sex distribution, Stamen, Staminode, Zygo-(morphism).

CLASSIFICATION

Nomenclature; and of. Key to Families at end of book.

FORMS OF VEGETATION; GEOGRAPHICAL DISTRIBUTION

Beach-jungle, Chaparral, Climbing Plants, Dispersal, Epiphytes, Floral regions, Halo-(phytes), Insectivorous Plants, Mangroves, Myrme-cophilous Plants, Parasites, Pitcher Plants, Plant formations, Saprophytes, Water Plants, Xerophytes, Zones of Vegetation.

ECONOMIC BOTANY

Alcohol, Alkaloids, Arrowroot, Bamboo, Bark, Camphor, Cinnamon, Condiments, Cotton, Drugs, Dyes, Ebony, Economic Botany, Economic Products, Edible Products, Fibres, Fodder, Foliage Plants, Grass, Gum, Guttapercha, Lac, Latex, Mucilage, Oil, Ornamental Plants, Poison, Resins, Rubber, Sugar, Tan, Timber.

EXPLANATORY INTRODUCTION

The Index of English names, technical terms, &c., which formed Part III of former editions, is now incorporated with the list of genera, so that the work forms one dictionary from end to end, with the exception of the key to the families at the end of the book.

. All the genera of Bentham-Hooker, Engler-Prantl, and Linnaeus are now included, as well as all given in the *Index Kewensis* and Supplements (except many synonyms), together with a large number published since the last Supplement, and which, by the kindness of the Director of Kew, I have been able to obtain from the MS lists kept at Kew. The most recent of these are given in a little Supplement at the end of the main dictionary, and I hope to bring this supplement up to date at intervals during the currency of the edition, adding the entries later to the body of the work so far as the padding will allow. Besides the genera, all families and higher divisions are also included.

The name of the genus is followed by the name of its author, often abbreviated, e.g. R.Br. (cf. Abbreviations), on the system explained under Nomenclature. The original description of the genus may be found by reference to the *Index Kewensis*. In the same way, the author is given after every species quoted, and the original description may be discovered from the same book.

Owing to the continual changes that go on in many families and genera, names are often reduced to synonyms; a great number of such are given in this book, chiefly those used in well-known floras; e.g. Abildgaardia Vahl = Fimbristylis Vahl. Under some of the best known genera, e.g. Abies, a few specific synonyms have also been given, especially names frequently met with in gardens, and opposite to each of these is given the name now generally used; thus Abies alba Michx. must be looked for under Picea, Abies Donglasii Lindl. under Pseudotsuga, and so on. It is very difficult to decide when divergence of two forms is sufficient to entitle them to rank as genera, and this difficulty is the cause of much synonymy. A genus A is established by one author, and then it is discovered not to differ sufficiently from another genus B, established by the same or another author, to remain as an independent genus. A is therefore merged in B and becomes a synonym. The

species of A retain as far as possible their old specific names when placed in B. When an entry such as "Abildgaardia Vahl = Fimbristylis Vahl p.p." is found, it means that the genus Abildgaardia as established by Vahl is merged in his Fimbristylis. Many of the species change their names, but some retain their specific names, when the name is not already occupied. This latter case is often indicated by putting the name of the old genus in brackets after that of the new, thus, F. (A.) fulvescens. In many cases the names of some of the genera thus merged in other genera are indicated thus: Axinandra Thw. (BH. incl. Naxiandra Krasser); no attempt however has been made to give all such cases or a fraction of them, but only a few of the more important. In particular those have been given where the genus as here defined differs from the definition in Engler and Prantl's Natürliche Pflanzenfamilien or Bentham and Hooker's Genera Plantarum by the inclusion and exclusion of other genera.

The name of the genus is followed by that of the family to which it belongs, and after this is often a number (in brackets) indicating the section of the family, thus Acacia belongs to Subfamily I and Tribe 2 of Leguminosae. The general plan upon which the book has been constructed, and the necessity for condensation, render it essential, if the full advantage is to be derived from its use, that the student should refer to the family as well as the genus. There he will find the important general characters possessed by its members, and should examine the genus to see in what it agrees, and in what it disagrees, with these. A further reference to the classification given at the end of the article upon the family will point out the special characters to be looked for in the genus as a member of some particular sub-family or tribe. In this way a large amount of information about the particular plant in question may be obtained, and at the same time the student will get into the way of regarding plants not as so many independent and disconnected units, but as related members of one great whole. In this way too he will soon acquire an appreciation of the relative importance of the different characters in classification and will learn to recognise the approximate relationships of most plants after a brief inspection, or even at sight.

The families are those given by Engler in his Syllabus and in Die natürlichen Pflansenfamilien, but sufficient reference is made to Bentham and Hooker's system of classification to enable any one who may prefer to use that system to do so.

The name of the family is followed by a statement of the number of

species in the genus, and its geographical distribution. The number, unless very small, is always only an approximation; new research is always bringing new species to light, splitting up older ones, or combining two or more into one. This is all the information that is given about a very large number of the genera; only when a genus presents some character of interest which is not common to the order or group, is any particular mention made of it. The biological peculiarities of the most important genera are dealt with pretty fully, but much has been omitted. Thus in dealing with the pollination-methods of flowers a selection of important genera, illustrating the various methods, has been made for description; so too with epiphytes, xerophytes, the morphology of parts, and so on. General discussions of all these subjects will be found under the title of the subject itself, and numerous examples are there quoted; these examples are mostly dealt with more fully. Numerous cross-references to other articles, e.g. Buds, Dichogamy, Fruit, Leaf, Parasite, Xerophyte, &c. (cf. Index), are made, and should be looked up.

While in the morphology, &c. a selection has thus been made of genera for treatment, this is less the case with economic botany. This has been more fully treated, only a comparatively few genera being omitted. Space, however, has not permitted of a detailed description of economic products or the way in which they are obtained; for this reference must be made to other works (see Literature).

Turning now to the other articles upon the families, the same general principles apply to them. After the name of the family is given the order to which it belongs, marked EP. or BH. if necessary to distinguish between these systematists. This should be looked up in the key at the end; this will show the families which are most nearly related to the one under consideration, and the characters that distinguish one from the other can be made out by comparison of their descriptions. The student should always endeavour to make out why a given family is classified in the position assigned to it. When the family as defined by Engler differs from that defined by Bentham and Hooker, as is so often the case, an attempt should be made to discover the reasons for the difference.

After the position of the family in the system follows the number of its genera and species, the morphology and natural history of its vegetative and reproductive organs, its economic products, and finally, in the case of the more important families, its classification into sub-families and tribes, with the more important genera belonging to each. The student should work through this part and study as many of the genera

as possible before leaving the family. This is easily managed in dealing with the outdoor collection in our botanic gardens.

No particular attempt is made in the book to avoid technical terms. When a term or abbreviation is used that the reader does not understand he should look it up in the Dictionary, or under Abbreviations.

To save space, in many cases in which there are several words in use beginning with the same prefix, e.g. aniso-, apo-, endo-, epi-, geo-, gyno-, halo-, heter-, iso-, phyllo-, poly-, sym-, xero-, &c., all are given under the heading of the prefix. If a word is looked up as a whole, therefore, and not found, reference should be made to the prefix before saying that it is omitted from the Dictionary.

Many genera are described by different authors under different spellings, and the most common and important of such cases are included; thus Prunella is also described under Brunella, Eleocharis also under Heleocharis, &c. A (fl.-class), fls. with freely exposed honey; Acer, Euphorbia, Galium, Hedera, Ilex, Rhamnus, Saxifraga, Umbelliferae.

A-, An- (Gr. prefix), not.

Aaron's Beard, Hypericum calycinum L.

AB (fl.-class), fls. with partially concealed honey; Caltha, Crataegus, Cruciferae, Fragaria, Potentilla, Ranunculus, Sedum.

Ab (Lat. prefix), from; -axial (side), away from axis; -breviated, shortened; -errant, differing from type; -normal, varying from the rule; -original, strictly native; -ortion, imperfect or arrested development; -rupt, terminating suddenly; -sciss-layer, separation-layer for dropping the l.; -sorption, taking up of fluids by r. or l.

Abaca, Manila hemp, Musa textilis Née.

Abasoloa La Llave. Compositae (5). 1 Mex.

Abatia Ruiz et Pav. Flacourtiaceae (7) (Samydaceae, BH.). 5 trop. S. Am. Fl. apet. L. opp.

Abauria Becc. (Koompassia Maingay, EP.). Legum. (11. 5). 2 Malaya. Abbevillea Berg. = Campomanesia Ruiz et Pav. p.p. (Myrt.).

Abbottia F. Muell. Rubiaceae (11. 2). 1 N. Austr.

Abbreviations. Descriptions of floral morphology are largely given in the terms of Floral Formulae, explained under that heading. When the name of a genus or family is repeated in the article dealing with it, it is represented by the initial letter only, e.g. A. for Abies. The name of a family is sometimes abbreviated by the omission of the terminal aceae, &c.; e.g. Capparid., Compos. The term 'warm' is sometimes used instead of 'tropical and subtropical.' The expression BH. after a genus or family, &c., means "as defined by Bentham and Hooker in their Genera Plantarum"; EP. means "as defined by Engler and Prantl in the Pfansenfamilien and Pfanzenreich."

The following mathematical and other symbols are largely used:

¥, hermaphrodite

ð, male

?, female

() enclosing P, K, C, A, or G, united or concrescent

G superior, G inferior, ovary

∞, indefinite, numerous ×, hybrid

\$, section (of sp. or genus)

@ or O, annual

or ⊙, biennial

24 , perennial

h, tree or shrub
>, more than

<, less than

±, more or less than

1, at right angles to

parallel to

=, equal to, merged in
!, seen by author
μ, micromillimetre, το¹υ mm.
ψ, actinomorphic

↓ , zygomorphic

*, N. hemisphere

*, S. hemisphere
|*, Old World

*|, New World

The following abbreviations are largely employed in this and other botanical books:

Mill. = Picea excelsa; A. rubra Poir. = Picea r.; A. vulgaris Poir. = A. pectinata. Coniferae (Pinaceae, 2; see C. for generic characters). 24 N. temp.

The firs are evergreen trees with needle l. borne directly on the stems.

No short shoots. On the main stem the symmetry is radial, whilst on the horizontal branches the l. twist so as to get their surfaces all much in one plane. If the top bud or leader be destroyed, however, a branch bud below it takes up the vertical growth and radial symmetry. Cones large, arranged much like Pinus; ? often brightly coloured, though wind-tertilised. The carpel-scales are large and appear on the outside of the cone between the ovuliferous scales. The cone ripens in one year.

A. pectinata DC. (silver-fir, Mts. of S. Eur.) yields a valuable wood, 'Strasburg' turpentine, &c. A. balsamea Mill. (E. N. Am., balsam fir) yields the turpentine known as Canada balsam. Many others yield useful timbers and resins. Handsome trees; commonly cult. are A. concolor Lindl. et Gord. (N. W. Am.), A. firma Sieb. et Zucc. (Japan), A. nobilis Lindl. (N. W. Am.), A. Nordmanniana Spach (Caucasus), A. Pinsapo Boiss. (Spain), A. Webbiana Lindl. (Himal.).

Abietineae, a tribe of Coniferae Pinaceae.

Abutilon Tourn. Malvaceae (2). 120 trop. and sub-trop. No epicalyx. Fl. mech. like Malva silvestris, but some are self-sterile; the sta. do not move down, and the styles emerge through the anther-mass. Many visited by humming-birds. A. Avicennae Gaertn. cult. in China for fibre China jute.

"Abyssinian banana, Musa Ensele J. F. Gmel.; primrose, Primula. Acacallis Lindl. (Aganisia Lindl. EP.). Orchid. (11. 13), 1 N. Brazil. Acada (Tourn.) L. Leguminosae (1. 2). 550 trop. and sub-trop.,

mostly trees (wattles); typical leaf-form bipinnate with leaflets and small scaly stips. About 300 sp., forming the § Phyllodineae (chiefly in Austr., where they are char., and Polynes.), have simple leaflike phyllodes, i.e. petioles (or primary axes; cf. Nature, 5 Aug. 1920,

p. 724) flattened with their edges upwards, exposing less surface to radiation. Inspection shows the phyllode to be a leaf-structure with axillary bud, but not that it is not a l. turned edgewise, Occasionally there are reversions though it shows no twist. to type (i.e. to the ancestral form) on the plant, some phyllodes occurring with leaf-blades of the ordinary bipinnate type. This is still better seen in germinating seedlings. The first I. are typical bipinnate 1., followed by others with slightly flattened stalks and less blade, and so on, until finally only phyllodes are produced. In A. alata R.Br. and others, the phyllodes are decurrent on the stem, like the l. of thistles. In many the stips, are repres, by large thorns, swollen at the base. In A. sphaerocephala Cham. et Schlecht. (Cent. Am.), the thorns are inhabited by colonies of ants, which bore into them and clear out the internal tissue. The ants live on the A. and are fed by it. Extrafl. nectaries occur on the petioles, and yellow sausage-shaped food-bodies on the tips of the leaflets. These consist of parenchymatous cells containing food-stuffs, and are eaten by the ants. If attempt be made to interfere with the tree the ants rush out. (Cf. Cecropia, and see Nature, Aug. 1893, for an account of the leafcutting ants: and cf. Schimper, Plant Geogr. p. 140. This was the first case of myrmecophily (symbiosis with ants) discovered; see Belt's Naturalist in Nicaragua.) Other sp. are myrmecophilous also.

A few are twiners, others hook-climbers. Most are xerophytes, often forming char. features in vegetation and scenery, e.g. the babul (A. arabica Willd.) with its low, spreading habit, is almost the only tree in many parts of the dry plains of India, and others are common in S. Afr. &c. In Austr. (esp. S. Austr.) the A. take a great part in the formation of the scrub, a concourse of shrubby plants of many genera, which covers the almost waterless country with a waste of veg. about 6—10 feet high, of a general bluish green effect, and with few

herbs or grasses beneath.

The fl. (diagram, see order) has ∞ long sta., affording little protection to the pollen. In A. homalophylla A. Cunn. (S. E. Austr.;

Myall) the seed hangs out on a long red funicle.

Many valuable products. A. Senegal Willd. (Soudan) yields the best gum-arabic; the gum exudes from the branches principally during the prevalence of the dry desert winds. Other sp. yield inferior qualities. A. catechu Willd. (E. Ind.) yields catechu or cutch (used in tanning), by digestion of the wood in hot water. With this the true khaki cloth is dyed and shrunk. A. decurrens Willd. (Austr.; black wattle), A. pyrnantha Benth. (S. E. Austr.; golden wattle), A. dealbata Link (Austr.; silver wattle) &c. yield good tanbark, cult. in Natal. That of A. arabica Willd. is largely used in India. The wood of many is valuable, esp. Australian black-wood, A. melanoxylon R. Br. Many have sweetly scented fis.; those of A. Farnesiana Willd. (trop.) are the Cassie flowers of perfumery. A. armata R.Br. (temp. Austr.; kangaroo thorn), A. horrida Willd. (S. Afr.) &c. form good hedges or sandbinders.

Acacia, false, Robinia Pseud-acacia L.

Accena L. Rosaceae (III. 5). 120 **, Mex., Calif., Polynes. Fr. hooked. Some sp. bud from junction of leaf and stalk.

Acajou (W. I.), Guarea trichilioides L.

Acaju, Cashew, Anacardium occidentale L.

Acalypha L. Euphorbiaceae (A. 11. 2). 400 trop., S. Afr. Anther lobes twisted; stigmas branched. Several cult. for varieg. 1.

Acampe Lindl. Orchidaceae (II. 16). 12 Indomal., China, (Afr. BH.).

Acamptocladus Nash (Eragrostis Host, p.p.). Gramin. (11). 1 S.W. U.S.

Acamptopappus A. Gray (Aplopappus Cass. BH.). Comp. (3). 2 N. Am. Acanthaceae (EP., Bll.). Dicots. (Sympet. Tubiflorae). 240 gen., 2000 sp., esp. trop. but also Medit., U.S., Austr. 4 chief centres of distr.: Indomalaya, char. by Strobilanthes and Andrographidae, Afr. (Thunbergia and Barleria), Braz. (Mendoncia and Ruellia), and Centr. Am. (Aphelandreae and Odontonema). Many biological types -climbing plants, xerophytes, marsh plants, &c. - and much variety in habit. Very many in damp places in trop. forests. Trees are rare; most are shrubs or herbs with opp., usu. decussate and entire, exstip. l., usu. thin. Cystoliths, visible as streaks or protuberances, are usu. common on 1. and stems. Infl. most commonly a dich. cyme, in its ultimate branchings tending to monoch., and frequently condensed in the leaf-axils as in Labiatae. Racemose infls. also occur, and sol. fl. are common. Bracts and bracteoles usu. present, often coloured; the latter frequently large, # enclosing the fl.

Fl. \$, hypog., zygom., usu. with nectariferous disc below ov. K (5-4), C (5-4), commonly two-lipped (upper lip sometimes not developed, e.g. in Acanthus). A rarely 5, usu. 4 or 2 epipet., usu. exserted; 1-3 stds. frequently present; anthers often with one lobe smaller than the other, or abortive; connective often long (cf. Salvia). The pollen exhibits great variety of patterns (see Nat. Pfl.); these are generally constant in the genus, and may be used in classification. G (2), 2-loc. with axile plac. each with 2-∞ usu. anatr. ov. in two rows. Style usu. long with two stigmas, the post. often smaller. The general arrangement of the fl. for visits of insects, protection of pollen,

&c. is like Labiatae or Scrophulariaceae.

Fr. a bi-loc. caps. (with few exceptions), usu. ± stalked, loculic. to the very base. Seeds usu. exalb. Their modes of distribution are interesting (see Nat. Pfl.). The capsules of § 1v explode and the seeds are thrown out, largely by the aid of peculiar hook-like outgrowths from their stalks (retinacula or jaculators). Many have superficial scales and hairs which on wetting become mucilaginous (cf. Linum, Collomia), e.g. Crossandra, Ruellia, Blepharis.

Classification and chief genera (after Lindau):

I. NELSONIOIDEAE (Ovules ∞ ; jaculators papillashaped): Ebermaiera, Nelsonia.

II. MENDONCIOIDEAE (Ov. 4, seeds not more than 2. Drupe; no jac.): Mendoncia.

III. THUNBERGIOIDEAE (Ov. 4. Capsule; jac. papillalike): Thunbergia.

IV. ACANTHIOIDEAE (Ov. 2-\infty. Capsule; jac. hookshaped):

A. Contortae (cor. conv., or never ascendingly imbr.): Strobilanthes, Ruellia, Eranthemum, Barleria.

B. Imbricatae (cor. ascendingly imbr., or with no upper lip): Blepharis, Acanthus, Crossandra, Aphelandra, Andrographis, Dicliptera, Fittonia, Odontonema, Justicia, Beloperone.

Acanthura Lindau. Acanthaceae (IV. A). 1 Mattogrosso.

Acanthus Tourn. ex L. Acanthaceae (IV. B). 25 trop. and sub-trop., As., Afr., Eur., mostly xero. with thorny I. (those of A. spinosus L. furnished, it is supposed, the pattern for the decoration of the capitals of Corinthian columns). A. ilicifolius L. is part of the palaeotrop. ACER 11

mangrove (q.v.) veg. F1. a large bee-f1.; there is no upper lip to the C, and the protection of the pollen, &c. is undertaken by the K. The anthers form a box by fitting closely together at the sides, and shed their pollen sideways into it, where it is held by hairs till an insect probing for honey forces the filaments of the sta. apart and receives a shower of pollen on its head (loose-pollen mechanism, cf. many Scrophulariaeeae, Ericaceae, &c.). In the young fir. the style is behind the anthers, later on it bends down so as to touch a visiting insect. The fr. explodes; large 'jaculators' on the seeds.

Acarna All. = Atractylis L. p.p. (Compos.).

Acardomatia, cavities mite inhabited, Anamirta, Fraxinus, Parameria.

Acaulescent, almost stemless; acaulis (Lat.), without visible stem.

Accessory branch, bud, supernumerary in same axil, see Buds; organs of flower, the perianth.

Acclimatisation, adaptation to new climate.

Accrescent, enlarged and persistent.

Accumbent, see Cruciferae.

Aceituna, Symplocos.

Acentra Phil. (Hybanthus Jacq. p.p. EP.) Violaceae. 1 Chili.

doer (Tourn.) L. Aceraceae (Sapind. BH.). 150 N. temp., esp. in hill districts (A. pseudoplatanus L., sycamore, and A. campestris L., maple, in Brit., the latter native) and trop. mts.; many in China and Japan. Trees and shrubs, with opp. exstip. l., deciduous or evergreen. L. often simple entire, more commonly 3. or 5-lobed, occasionally cpd. One may go through a collection of A. in an herbarium or elsewhere, comparing the l. as to degree of development of the drip-tips (acum. apices to easily wetted l., from which the water drips off rapidly after a shower, cf. Ficus) noting the kind of climate from which each has come. There is a correlation between length of tip and wetness of climate.

Large winter buds, covered by scale l. In many sp. transitional forms may be seen as the bud elongates in spring, between the scales and the green l., showing that the scale = not the whole l., but the leaf base. In the § Negundo there are no scales, but the bud is protected by the base of the petiole of the l. in whose axil it arises.

The l. commonly exhibit varnish-like smears, of sticky consistence, known as honey-dew, the excretion of aphides which live on the l.; the insect bores into the tissues, sucks their juices, and ejects a drop of honey-dew on an average once in half-an-hour. In passing under a tree infested with aphides one may sometimes feel the drops falling like a fine rain (see Pithecolobium). The fluid is rich in sugar. When the dew falls the hygroscopic honey-dew takes it up and spreads over the l.; then later in the day evap. reduces it to a varnish on the surface. Many other trees exhibit this phenomenon, s.g. lime, beech, oak (Büsgen, Der Honigthau, Jena).

Fls. in racemes, sometimes contracted to corymbs or umbels, reg., polyg., not conspic.; formula usu. K5, C5, A4+4, G (2). Apetaly in some. 3 cpls. are frequent, esp. in the end fl. of a raceme. If fls. protandrous; honey freely exposed on the disc (fl.-class A), available to insects of all kinds. Fr. a samara. In germination, the

long green cotyledons come above the soil almost at once.

of the E.U.S. yield maple sugar (2-4 lb. a tree) obtained by boring holes in February and March and collecting and evaporating the juice. Many yield good timber and charcoal. A number of Japanese sp., with prettily shaped or varieg. l., cult. as orn. shrubs. Aceraceae (Sapind. p.p. BH.). Dicots. (Archichl. Sapindales). 2 gen. (Acer. Dipteronia) with 150 sp. N. temp. and trop. mts. Trees and shrubs; 1. opp., petiolate, exstip., simple entire or more often palmately or pinnately lobed or cpd. Infl. racemose, corymbose, or fasciculate. Fls. reg., andromonoec., androdioec., dioec., &c., 5-4-merous, usu. dichlam. Disc annular or lobed or reduced to teeth, rarely absent. A 4-10, usu. 8, hypog., perig., or on disc; & fir. with rudimentary G. G (2), 2-loc., lat. compressed; styles 2, free or joined below; ov. 2 in each loc., orthotr. to anatr., with dorsal raphe. Fr. of 2 samaras, separating when ripe. Seeds usu. solitary, exalb., the cotyledons irreg. folded. Many yield good timber, sugar, &c. (cf. Acer). Largely represented in the Tertiary. Aceranthus Morr. et Decne. (Epimedium Tourn. EP.). Berberidaceae. 3 Chi., Jap. Aceras R. Br. Orchidaceae (II. 1). 1 Eur. (incl. Brit.), Medit., A. anthropophora R.Br., the man-orchis. Like Orchis. Agave L. Amaryllidaceae (11). 275 trop. Am. and S.U.S., incl. A. americana Linn. (Century plant, Maguey, American aloe). The short stem grows in thickness like Yucca, bearing a rosette of large fleshy l. coated with wax; only 2 or 3 l. form in a year. During 5 to 60 or perhaps 100 years (hence the name), depending on climate, richness of soil, &c., the plant is veg., and stores up in the l. an enormous mass of reserves. At length it flowers, a gigantic term. infl. coming rapidly out, sometimes reaching 20 feet, and bearing many fis. When the fr. is ripe the pl. dies. Veg. repr. in two ways—by suckers from base of stem, and by formation of bulbils in place of many fls.

The rush of sap to so large and so rapidly developed an infl. is very great; the Mexicans cut off the young fl. head and collect the As much as 1000 litres are said to be given by one plant. The fermented juice (pulque) is a national drink; from it they distil a spirit called mescal (cf. Cocos). Many yield useful fibres. The best are sisal hemp and henequen, given by A. sisalana Perrine, and A. fourcroydes Lem., cultivated in Yucatan, the Bahamas, India, &c. Others yield fibres variously known as pita, istle, ixtle, lechuguilla, keratto, &c. See Rep. Miss. Bot. Gdn. 1896, p. 47; Kew Bull. 1802, p. 21, Tropenpfl. 1899, p. 337; Dodge, Useful Fiber Plants (Bull. U.S. Dpt. Agr.), &c.

Angiopetalum Reinw. Myrsinaceae (inc. sed.). I Java.

Angiopteris Hoffm. Marattiaceae (1). 65 Madag., Indomal., A. evecta Hoffm. Large ferns with the sori not united into synangia as in most M. Annulus like that of Osmundaceae at apex of sporangium. The r. arise close to apex, and burrow down and outwards through the stem and leaf-bases, emerging some distance down.

Angiospermae. One of the two great divisions of Spermaphyta, distinguished from Gymnosperms by the fact that the cols. are so infolded or arranged as to form an ovary in which the ovules are borne.

Endosperm formed after, instead of before fert.

All A. possess true fl., the essential parts of which are sta. and cpls. The former bear pollen-sacs (= microsporangia of Pteridophyta), the latter ovules (megasporangia). The ovule is always enclosed in the cpl.; it has two (or one) integuments, and usually one embryosac (more in some chalazogamic forms, Loranthaceae, &c.). The pollen-tube may enter by the micropyle or by the chalaza (cf. Chalazogamae). Parthenogenesis, or development of the ovum into an embryo without fert., occurs in Antennaria, Alchemilla, Hieracium, Houltuynia, Thalictrum, Wikstroemia, &c., embryo formation by adv. budding in Alchornea, Citrus, Euonymus, Funkia, Nothoscordum. &c., apogamy (cf. Filicineae) in Balanophora.

A. are divided into Mono- and Di-cotyledons (cf. classification at

end of the book).

Apocynaceae (EP., BH.). Dicots. (Sympet., Contortae; Gentianales BH.; pp. xliii, liii). 180/1400, mostly trop., a few temp. Usu. twining shrubs, rarely erect; many large trop. lianes. Latex present; bundles bi-collateral. L. simple, opp. or alt. or in whorls of 3, entire, usu, with close | lat. veins, rarely with small interpetiolar stip. Primary type of infl. a panicle, often going over into dich. cyme or cincinnus; br. and bracteoles present. Fl. \$, reg., usu. 5-4-merous. K (5), deeply lobed, quincuncial with odd sep. post., often with glands at base; C (5), usu. salver- or funnel-shaped, often hairy within, conv. or rarely valv., tips often conv. the opp. way, pets. sometimes asymmetric; A 5, alt. with C, epipet., with short incl. filaments; anther lobes full of pollen to base, or empty below and prolonged into rigid spines, usu. united to stylar head; disc usu. present. G or 1-inf. (2), or 2 (united by style), or more, 1-2-loc. with ∞ -2-4-6 ov. in each loc., anatr., pend.; style usu. simple with thickened head, and ring of hairs below it. Fr. 2 follicles, berry, caps., or 2 indeh. fr.; seeds usu. flat, often with crown of hairs. Embryo straight, with endosp. or none. When the stylar head is large the stigma is at its edge or under surface, and self-fert, is almost impossible. Cf. Apocynum. Many are showy ornamentals. Landolphia, Carpodinus, Hancornia, Funtumia, Mascarenhasia, &c. yield rubber, and several give useful drugs, alkaloids, &c.

Classification and chief genera (after Schumann): cf. Asclep.

 PLUMIEROIDEAE (sta. free or loosely joined to stylar head; thecae full of pollen, rarely with spines; seeds usu. hairless):

1. Arduineae (syncp.; style not split at base); Arduina, Allamanda, Landolphia, Carpodinus, Hancornia.

Pleiocarpeae (apocp.; style split at base; > 2 cpls.):
 Pleiocarpa.

3. Plumiereae (do.; 2 cpls.): Plumiera, Alstonia, Aspidosperma, Amsonia, Lochnera, Vinca, Tabernaemontana, Voacanga, Alyxia, Rauwolfia, Ochrosia, Cerbera.

II. ECHITOIDEAE (sta. firmly joined to stylar head; thecae empty at base, and with spines; seeds hairy):

 Echitideae (anthers included): Echites, Dipladenia, Odontadenia, Mandevilla, Baissea, Funtumia, Mascarenhasia, Apocynum, Nerium, Strophanthus.

2. Parsonsieae (anthers exserted): Wrightia, Parsonsia, Lyonsia, Malouetia, Forsteronia, Prestonia.

Apocynum (Tourn.) L. Apocyn. (11. 1). 25 N. temp. Some cult., incl. A. androsamifolium L. (American fly-trap), with fl. mech. like Asclep. Stylar disc stigmatic below, surrounded by rigid lignified sta. An insect withdrawing proboscis usu. brings it up the narrow slit between sta., at whose base is a drop of cement. Higher up the anthers open lat. and thus pollen is attached to proboscis, but strength

is needed, and small insects are usu, caught, as may be seen in gardens. Seeds hairy (wind carriage).

Arabis Linn. Cruciferae (4). 220 N. temp., S Am., 5 Brit. (rockcress). Cult. orn. fl.

Araceae (EP.; Aroideae BH.). Monocots. (Spathiflorae). 107 gen., 1900 sp., trop. and temp. (92 % trop.). Many types of veg. habit herbs large and small, with aerial stems, tubers or rhiz., climbing shrubs, climbing epiph., marsh pl., one water pl. (Pistia) &c. In a few Pothoideae the stem is monopodial, but in most A. it is sympodial. Each joint of the sympodium begins as a rule with one or more scale 1. before bearing fol. 1. Accessory (collateral) buds often found in the leaf axils. Sometimes, as in Anthurium, Philodendron &c., the axillary shoot is 'adnate' to the main axis for some distance (cf. Solanaceae, Zostera &c.). The buds usually appear in the l. axils, but often get pushed to one side, and sometimes (e.g. Pothos) break through the leaf-bases as in Equisetum.

L. of many types. Pinnately and palmately divided 1. are frequent. but development not like that of such leaves in Dicots. Holes are

present in the l. of Monstera. See Monstera, Rhaphidophora, Philo-

dendron, Helicodiceros, Dracontium, Zamioculcas, &c.

Roots adv. and mostly formed above ground in the larger forms. Two types of aerial r.—climbing and absorbent. The former, like ivy, insensitive to gravity, show great negative heliotropism; they cling closely to the support and force their way into the crevices. The latter, insensitive to light, respond markedly to gravity; they grow down to the soil and enter it, branching out and taking up nourishment.

The larger trop. A. show interesting stages in the development of epiphytism. The climbing forms grow to considerable size and form longer and longer aerial r. as they grow upwards. The original r. at the base thus become of less and less importance and they often die away together with the lower end of the stem, so that the plant thus becomes an epiph. Of course, as it still obtains its water &c. from the soil, it is not an epiph. in the sense that e.g. many Orchids or Bromeliaceae are such, and it is evident that if this method of becoming epiph. were the only one found in the order, these plants could with no more justice be classed as true epiph. than the ivy which may often be seen in the 'bowls' of pollard willows in Europe, and which has come there by climbing up the trunk and dying away It is found however that some sp. of Philodendron, Pothos, &c. are able to commence life as epiphytes. The fleshy fr. is eaten by birds and the seed dropped on a lofty branch. The seedling forms clasping r. and dangling aerial r. which grow steadily down to the soil, even if it be 100 feet or more away. It is hardly possible to suppose that these true epiph. sp. have been evolved in any other way than from former climbing sp. Lastly, some sp. of Anthurium &c. are true epiph. without connection with the soil (e.g. A. Hugelii Schott = A. Hookeri Kunth.); they have clasping r. and also absorbent r. which ramify amongst the humus collected by the pl. itself. The aerial r. of some A. possess a velamen like Orchids. The 1. of Philodendron cannifolium Schott have swollen petioles full of large intercellular spaces lined with mucilage. When rain falls these fill with water and act as reservoirs. [Cf. Schimper's Epiph. Veg. Amerikas.

Fls. without br., usu. massed together on a cylindrical spadix enclosed in a large spathe; the spadix usu. terminates a joint of the sympodium (the 'continuation' bud is generally in the axil of the l. next but one before the spathe), so that there is only one formed each year. Fl. & or monoec. (dioec. in Arisaema), with or without P. Sta. typically 6 but usually fewer (down to 1), often united into a synandrium (e.g. Colocasia, Spathicarpa); in Ariopsis the synandria again united to one another. Stds. often present, and these also may be fused into a synandrodium as in Colocasia. G with much variety of structure; frequently reduced to 1 cpl. Berry. Outer integument

of seed often fleshy. Endosperm or none.

Fls. usu. protog. (even when monoec.). In many gen. (incl. most Eur.) the smell is disagreeable and attracts carrion flies as pollen carriers (see Arum, Dracunculus, Helicodiceros, &c.).

Many A. contain latex, which is usually poisonous but is dispelled

by heat. The rhizomes of many sp. contain much starch and are used as food (Caladium, Colocasia, Arum, &c.).

Classification and chief genera (after Engler): Cf. Pfl. R.

The grouping of the A. is very difficult and account has to be taken of histological as well as external characters.

I. POTHOIDEAE (land pl.; no latex or raphides; l. 2-ranked or spiral; lat. veins of 2nd and 3rd order netted; fls. usu. \(\foat{y}\); ov. anatr. or amphitr.): Pothos, Anthurium, Acorus.

II. MONSTEROIDEAE (land pl.; no latex; raphides; lat. veins of 3rd, 4th, and sometimes 2nd orders netted; fl. y, usu. naked; ov. anatr. or amphitr.): Rhaphidophora, Monstera, Spathiphyllum, Epipremnum.

III. CALLOIDEAE (land or marsh pl.; latex; fl. usu. §; ov. anatr. or orthotr.; l. never sagittate, usu. net-veined):

Symplocarpus, Calla.

IV. LASIOIDEAE (land or marsh pl.; latex; fl. y or & ?; ov. anatr. or amphitr.; seed usu. exalbum.; l. sagittate, often much lobed, net-veined): Dracontium, Amorphophallus.

V. PHILODENDROIDEAE (land or marsh pl.; latex; fl. naked, unisex.; ov. anatr. or orthotr.; seed usu. album.;

1. usu. ||-veined): Philodendron, Zantedeschia.

VI. COLOCASIOIDEAE (land or marsh pl.; latex; fl. naked unisex.; sta. in synandria; ov. orthotr. or anatr.; seed album. or not; l. net-veined): Remusatia, Colocasia, Alocasia, Xanthosoma.

VII. AROIDEAE (land or marsh pl.; latex; l. various, netveined; stems mostly tuberous; fl. unisex., usually naked; sta. free or in synandria; ov. anatr. or orthotr.; seed album.): Spathicarpa, Arum, Dracunculus, Helicodiceros, Arisaema.

VIII. PISTIOIDEAE (swimming pl.; no latex; fl. unisex., naked; & fls. in a whorl, ? sol.): Pistia (only genus).

For further details of this most interesting order, see Engler in Nat. Pfl. and Pfl. R., from which much of the above is abridged.

[Placed in Nudiflorae by BH.]

Arachis Linn. Leguminosae (III. 7). 10 Brazil, Paraguay. A. hypogaea L. (ground-, earth-, or pea-nut), largely cult. in warm regions for its seeds, which are ed. and when pressed yield one of the many oils used in place of olive oil. The fl. after fert. bends down (cf. Linaria) and the elongation of its stalk forces the young pod under ground, where it ripens.

Aristogeitonia Prain. Euphorbiaceae (A. I. 1). 1 W. trop. Afr.

Aristolochia Tourn. Aristolochiaceae. 300 trop. and temp.; herbs with rhiz. or twining lianes. A. Gigas Lindl. (pelican flower) and others often cult. orn. fl. Many trop. sp. have a small l. surr unding the stem at the base of each ordinary l., and looking like a stip., but really the first l. of the axillary shoot, which grows very rapidly at first. In other cases this l. remains small and its shoot does not develope, so that it looks like an interpet. stip. In most several buds

form in each axil; the fls. usu. come from the upper ones.

A. Clematitis L. (birthwort) an escape in Brit. P tubular, hooded at top, and enlarged below round the gynostemium; this has 6 sessile extr. anthers below and as many stigmatic lobes above (really not the true stigmas, but-the connectives of the anthers, which have assumed stigmatic functions). The young fl. stands erect and its tube contains numerous hairs, jointed at the base so that they can easily be bent down but not up. No honey. Small flies enter the fl. at this stage and find the stigmas ripe, so that if they bear pollen from other fls. fert. takes place. They are unable to escape until in a day or two the pollen is shed, and the hairs wither, the fl. at the same time bending down (cf. Arum). In A. Sipho L'Hérit. (Dutchman's pipe) the P is bent like a siphon and has a polished interior surface.

Aristolochiaceae (EP. BH.). Dicots. (Archichl. Aristolochiales). 5 gen., 300 sp., trop. and warm temp., except Austr. Herbs or shrubs, the latter usu. twining lianes. L. alt., stalked, often cordate, usu. simple, exstip. Fl. §, epig., reg. or · [·. P usu. (3), petaloid; A 6—36, free, or united with the style into a gynostemium (cf. Asclepiads, Orchids, &c.). \$\overline{G}\$ 4—6-loc.; ov. \$\infty\$ in each loc., anatr., horiz. or pend. Caps. Embryo small in rich endosp. The A. are difficult to place in the system. They have been put near Dioscoreaceae, though not monocot. BH. place them in Multiovulatae Terrestres. Chief genera: Asarum,

Aristolochia.

Aristolochiales. The 15th order of Dicot. Archichl. Cf. p. xiv.

Articulate (1.), cut off by an absciss layer.

Articulated, jointed.
Artillery plant, Pilea.

Artocarpus Forst. Moraceae (11). 60 Indomal., China. Many show good bud-protection by stips. A. laciniata Hort. has large drip-tips (Acer, Ficus). Fls. monoec., the 3 in pseudo-catkins, the 3 in pseudo-heads. A multiple fr. is formed, the achenes being surrounded by the fleshy P and the common receptacle also becoming fleshy. The fr. contains much starch &c. and is a valuable food-stuff. Several sp. are cult. all over the trop., e.g. A. incisa L. (bread-fruit) and A. integrifolia L. (jak). The flesh has somewhat the texture of bread and is often roasted. The best cult. forms (cf. pear, banana, &c.) produce no seeds. The jak and others are caulifloral. Timber useful.

Artrolobium Desv. = Coronilla L., Ornithopus L., &c. (Legum.).

Arum (Tourn.) Linn. Araceae (VII). 12 Eur., Medit. A. maculatum L. (cuckoo-pint, wake-robin, lords and ladies, Brit.) is a perenn. tuberous pl. with monoec. fls.; ? fls. at base of spadix (each of 1 cpl., naked) and & above (each of 2—4 sta.), and above these again rudimentary & fls. repres. by hairs which project and close the mouth of the spathe. The foetid smell attracts flies, which enter the spathe, find the stigmas ripe, and are kept prisoners till the pollen is shed; then the hairs wither and escape is possible (cf. Aristolochia). Fr. a berry. The starch of the tubers was formerly used as food under the name Portland arrowroot, but it is difficult to get rid of the poisonous juices accompanying it. Other sp. are similarly used in Eur.

Arum lily, Zantedeschia aethiopica (L.) Spreng.

Asarabacca, Asarum europaeum L.

Asarca Poepp. ex Lindl. = Chloraea Lindl. (Orchid.).

Asarum (Tourn.) L. Aristolochiaceae. 30 N. temp. A. europaeum L. (asarabacca), an escape in Brit. (formerly medic.). Rhiz. below ground and creeping shoots above; the latter are sympodial, each annual joint bearing several scale l. below, then two green l. and a terminal fl. Fl. reg.; P (3), sometimes with 3 small teeth between the segments (perhaps remnants of a former inner whorl); A 12; G (6). The dark-brown, resinously scented fl. is visited by flies, and is very protog.; when the stigmas are ripe the sta. are all bent away, but later on they move up to the centre and dehisce extr. The P lobes are bent in at first towards the centre of the fl. and form a sort of prison of it, but afterwards gradually straighten.

Ascarina Forst. Chloranthaceae. 6 Polynesia.

Ascending (aestivation), cf. Aest.; (ovule), sloping upwards; (stem), do.-ascens (Lat. suffix), tending towards.

Asciadium Griseb. Umbelliserae (inc. sed.). 1 Cuba.

Ascidium, a pitcher.

Ascleptadaceae (EP. BH.). Dicots. (Sympet. Contortae). 320 gen., 1700 sp., mostly trop. (esp. Afr.), but a few temp. In veg. habit like Apocynaceae; some perenn. herbs, but most are climbing shrubs

or lianes, with simple, entire, opp., exstip. l. Latex is present. Many, esp. S. Afr. sp., xero.; some, e.g. Periploca, with much reduced I., others, e.g. Hoya, and still more, Stapelia, with fleshy stems. Epiphytes

also occur; cf. esp. Dischidia.

Infl. usu. of many fis. and cymose or racemose (raceme or umbel). In the former case it is dich, but as in Caryophyll, the one branch tends to outgrow the other, and a monoch. (cincinnus) may arise in later branchings. When infl. axillary, there is usu. only one at each node; in the axil of the other l. there is a veg. shoot, or nothing.

In some gen. (cf. Asclepias) the infl. is extra-axillary.

Fl. &, reg., 5-merous, usu. small. K 5, quincuncial, the odd sep. post.; C(5) usu. rotate or campanulate, with conv. or valvate aestivation. The essential organs (5 sta., 2 cpls.) are complex. The sta. and style are usu. united to form a gynostegium. The cpls. are free below as in Apocyn., but united at the tip with a common style; ov. sup. The head of the style is large and variously shaped, and the stigmatic surface is usually upon the edge or under side of it. To its margin are united the anthers of the 5 epipet. sta.; the filaments of these are short or non-existent. The pollen in § 1 is united merely in tetrads, in the higher group, comprising the bulk of the fam., into pollinia, as in Orchids. Usu. each anther contains two. In this group also there are curtain-like projections at the sides of the anthers, leaving a narrow slit between each pair of anthers.

The pollen is removed from the anthers by a curious mechanism the translator. This differs in the two suborders and so also does the fert. method. The translator always stands between two anthers and serves to carry away half the pollen from each of them. In the Periplocoideae it is a spoon- or funnel-like body with a sticky disc at the narrow end. Into it is shed the pollen from the two half anthers next to it, and as the sticky disc projects outwards in the male stage of the flower an insect will be likely to get it attached to its head, and carry it about like the pollinia of an orchid. In visiting a second flower the pollen may be placed on the stigmatic surface. In the Cynanchoideae, on the other hand, there are pollinia, and the translator has a different structure. It forms an inverted X-shaped organ, the foot of the Y being formed by the adhesive body (corpusculum); from this diverge the threads (retinacula) which are attached to the pollinia, one in each anther. An insect in obtaining honey catches its leg in the slit between the anthers, and in drawing it up removes the pair of pollinia. The threads as they dry contract on the inner side till the pollinia meet, thus closely clasping the insect's leg. In drawing the leg through a similar slit in another fl. the pollinia catch on the stigmatic under-surface of the stylar head. (Cf. Apocynum. which shows an approach to this mech.)

The backs of the anthers as a rule bear appendages (cuculli) forming a corona. In some cases it springs from the C. It may consist of small teeth, or be more complex, as in Asclepias and Ceropegia, and often takes up the functions of secreting and storing

the honey.

G (2), 2-loc., with ∞ anatr. ov. pend. from the ventral plac. Fr. a pair of follicles; seeds usu. crowned by a tuft of hairs for windcarriage. Endosperm slight, cartilaginous. Some give useful fibres.

Closely related to Apocyn., the only absolute distinction being the presence of translators in Ascl.; otherwise the two sub-orders of each form a corresponding series, and the lower one in each is almost as nearly related to the corresponding one in the other order as to the higher group in its own order. Placed in Gentianales by BH.

Classification and chief genera (after K. Schumann):

I. PER/PLOCOIDEAE (pollen in tetrads; translator spoonlike).

Periploceae: Stieptocaulon, Periploca.

II. CYNANCHOIDEAE (pollinia; corpusculum, &c.).

Asclepiadeae (pollinia pendulous on threads): Asclepias. Calotropis, Cynanchum.

Secamoneae (pollinia erect or horizontal, 4 in each anther): Secamone (only genus).

3. Tylophoreae (do. but 2 in each, erect): Ceropegia, Stapelia, Stephanotis, Hoya.

Gonolobeae (do. but 2 in each, horiz.): Gonolobus.

Asclepias L. Asclepiad. (II. I). 160 Am., Afr., esp. U.S. (silk-weeds). Herbs with umbellate infls. which spring from the stem between the petioles of the opp. 1. (cf. Cuphea), or above or below this. explanations exist, but which is right the evidence available does not show. Either the infl. is axillary to the l. below it and is 'adnate' to the stem (cf. Cuphea), or it is the termination of a shoot, and the stem is really a sympodium.

The cuculli of the anthers form little pockets, into which honey is poured by the horn-like nectaries that project from them. Insects walking over the fl. and sipping honey frequently slip their legs down the sides of the gynostegium, and in drawing them up catch in the slit between two anthers and remove the pollinia (cf. family). The process may be watched on A. Cornuti Decue. in gardens.

Aspiliopsis Greenman. Compositae (5). 1 Mex.

Aspleniopsis Mett. Polypodiaceae. I Melanesia.

Asplenium L. Polypodiaceae. 540 cosmop.; 11 in Brit., including A. Filix-foemina Bernh. (lady-fern), A. Ruta-muraria L. (wall-spleenwort), A. Trichomanes L. (spleenwort) and A. Adiantum-nigrum (black spleenwort). The var. clarissima of the lady-frame shows apogamy (see Filicineae, Lepto.). A. bulbiferum Forst. and other sp. are 'viviparous,' producing young plants on their leaves by vegetative budding (not to be confounded with apospory). A. Nidus

L. (the bird's nest fern) is an interesting epiphyte of the Old World tropics. It bears a rosette of leaves forming a nest in which humus collects; the roots ramify in this and obtain food and water. A. rhisophyllum Kunze is the walking fern, so called because the leaf-tips when they touch the soil bud into new individuals, and thus the plant spreads to some distance.

Asprella Schreb. = Leersia Sw. (Gramin.).

Assai palm, Euterpe edulis Mart.

Assegal wood, Curtisia faginea Ait.

Associations, plant, the grouping of pl. which occupies any definite uniform area and kind of land.

Assurgent, ascending.

Avellinia Parl. Gramineae (10). 2 Medit.

Avena L. Gramineae (9). 70 temp. and Mts. of trop.; 2 Brit. (oatgrass). A. sativa L., the cult. oat, is perhaps derived from A. fatua L. It is cult. in Eur. to 69½ N. and forms the staple of the food of a large population. It occurs in two chief forms, the common oat with open spreading panicles, and the Tartarian oat with contracted one-sided panicles. [See De Candolle's Orig. of Cult. Plts. p. 373.] The 2-6-flowered spikelets form a loose panicle. The paleae are awned, the awn of the inf. palea being usually twisted and hygroscopic. In A. sterilis L. the awns cross, and when wetted try to uncurl and thus press on one another till a sort of explosion occurs jerking away the fruits. [Cf. Bews, Grasses of the World.]

Avenastrum Jessm. (Avena L. p.p.). Gramineae (9). 10 S. Afr.

Averrhoa, L. Oxalidaceae. 2 trop. As. (?; long cult.; origin uncertain).

A. Bilimbi I. (blimbing) and A. Carambola L. (carambola) cult. for fr., which is borne on the older stems (cauliflory).

Averrhoidium Baill. Sapindaceae (II). 2 Brazil, Paraguay.

Averse, turned back.

Avicennia I. Verbenaceae (7). 4 warm, a constituent of the mangrove veg. (q v.). The seeds germinate in the fr., and they have aerial r projecting out of the mud like Sonneratia.

Avocado, Persea gratissima Gaertn. f.

Awl-wort, Subularia aquatica L.

Awn, a thread-like organ on a fr., Anthoxanthum, Erodium, Geraniaceae, Gramineae.

Axanthes Blume = Urophyllum Wall. (Rubiac.).

Axia Lour. (Boerhaavia L. p.p. EP.). Nyctaginaceae (Valerianaceae? BH.). 1 Cochinchina.

Axial, axile, belonging to the axis; -placentation, on the axis, cf. diagram of Guttiferae, Liliaceae.

Axil, the upper angle between a l. and the stem on which it is borne; -lary, in the axil. Cf. Buds, Concrescence, &c.

Axinaea Ruiz et Pav. Melastomaceae (1). 25 trop. Am.

Axinandra Thw. (BH. incl. Naxiandra Krasser). Melastomaceae (III). (Lythraceae BH.) I Ceylon.

Azalea Gaertn. = Loiseleuria Desv.; Azalea L. = Rhododendron L. p.p.

Asaleastrum Rydb. (Rhododendron p.p.). Ericaceae (I. 2). I N. Am. Asara Ruiz et Pav. Flacourtiaceae. 20 Mex., S. Am. Shrubs with alt. 1; one stip. is frequently almost as large as the 1. to which it belongs, giving the appearance of a pair of 1., not opp. Fl. apetalous; outer sta. often without anthers.

Azedarach Tourn. ex L. = Melia L. (Meliac.).

Aseredia Arruda (Cochlospermum p. p. EP.). Cochlosperm. 1 Brazil.

Asima Lam. Salvadoraceae. 3 S. Afr. to Phil. 1s. In the axils are thorns (the l. of an undeveloped shoot, cf. Cactaceae). Polypet.

Axolla Lam. Salviniaceae. 5 trop. and subtrop. General structure like Salvinia. Two I. are formed at each node, from the dorsal half of a segment of the apical cell; from the ventral half are formed roots and branches, but not at every node. The l. are all alike; each is bilobed and has a small cavity near the base, opening by a small pore, and inhabited by the Alga Anabaena. The r. hang freely down in the water; usually the root cap is thrown off after a time and the r. comes almost exactly to resemble the submerged I. of Salvinia. The sporocarps are formed in pairs (4 in A. nilotica) on the ventral lobes of the first I. of the branches. Each contains one sorus. The microspores are joined together into several masses in each sporangium by the hardened frothy mucilage (epispore, cf. Salvinia). Each of these massulae has its outer surface provided with curious barbed hairs (glochidia), and escapes on its own account. The megasporangium contains one spore. It sinks to the bottom; decay of the indusium frees the spore and it germinates, giving rise to a ? prothallus which floats about on the water and may be anchored to a floating massula by the barbs.

Azorella Lam. Umbelliferae (1. 2). 70 Andes to N.Z. Densely tufted xero. A. caespitosa Vahl. (balsam-bog, Falklands) forms tufts like Raoulia.

Asureus (Lat.), sky-blue.

B (fl.-class), fls. with fully concealed honey, Calluna, many Caryophyl laceae, Geranium, Gypsophila, Polemonium, Rubus, Thymus.

Bambarra groundnut, Voandzeia subterranea Thou.

Bamboo, a member of the 13th group of Gramineae, char. by stems that become woody below and often grow to great size. The tropforms usu. grow in clumps, which continually expand, the new shoots appearing at the outer side; the subtrop, and temp. forms are usu. continuous in their growth. There is a big rhiz, below ground and erect perenn, woody stems above, which appear in the rains (or spring) and grow rapidly to the full height, when the scale I. fall and the leafy branches spread out. Growth is very rapid in Dendrocalamus giganteus Munro, reaching as much as 41 cm. a day (cf. Lock, Ann. Perad. II. 211). Some climb. The height is often great, reaching to 120 feet in some forms.

Some fl. annually, others at longer intervals, and some are like Agave and Corypha, flowering only once, all together, and then dying down. They fl. only when in full leaf, and as the infl. grows the l. usu. fall. The seedlings grow for several years without forming tall shoots, producing large well-stored rhiz. They then send up shoots increasing in length from year to year.

Spikelets 2-\infty -flowered in racemes or panicles. Sta. usu. 6.

The economic uses of bamboos are very numerous, esp. in Asia. The stems are hollow, with cross partitions at the nodes, and the wood is elastic and very hard, owing to the deposition of silica in the cell walls. The stems are consequently very light and strong, and are also easily split. They are largely used in building, entire as posts, and split as roofing tiles, while the houses in Assam, Burma, and Malaya are often made of bamboo split finely, and woven into a kind of mat which is fastened upon bamboo posts. Bridges are often made of them, and they furnish water-pipes, water-vessels, gutters, floats, beehives, walking-sticks, pipes, flutes, masts, furniture, household utensils, agricultural tools, &c. The distichous bamboo shoot, with the side branches cut down to about 6 inches, is used as a ladder. Split bamboos, with the edges trimmed sharp, are used as grass cutters, and will keep lawns in good order. Finely split bam-boos are made into mats, blinds, rigging, baskets, fans, hats, coarse clothing, umbrellas, ropes, brushes, &c., esp. in Japan, where fine work is done in bamboo. Paper is made from bamboos in China and elsewhere. The stout stems of the male bamboo (Dendrocalamus strictus Nees) are used for the handles of lances. The stems cut into lengths form very useful flower pots, largely employed in tropical gardens. The young shoots are eaten like asparagus, and the poorer natives also use the seeds as food. In the stems of B. arundinacea Willd, curious concretions of silica are found, known as tabashir or bamboo manna, used in the East as a medicine in many diseases.

(See Kurz, Bamboo and its uses, Ind. Forester, 1876, and art. in Nat. Pfl. by Sir D. Brandis; Lock, on growth, in Ann. Perad. 11. 211; Freeman-Mitford, The Bamboo Garden.)

Begonia (Tourn.) L. Begoniaceae. 750 trop. and subtrop., esp. Am. Many cult. for handsome fls. and foliage. Most are perenn. herbs with thick rhiz. or tubers. Several climb by aid of roots like ivv. L. rad. or alt., in two ranks, with large stips. One side of the l. is larger than the other, whence the name 'elephant's ear,' by which they are sometimes known. The surface of the l. is easily wetted, and drip-tips are frequent (cf. Ficus). In the axils groups of little tubers are frequently found; these are not axillary branches, but are borne upon the true axillary branch, which does not lengthen. They also repr. easily by adv. buds which readily form on pieces of l. cut off and placed on the soil under suitable conditions of moisture &c. (the common mode used in horticulture). A callus forms over the wound, and in it there develops a meristem which gives rise to one or more buds.

Infl. axillary, dich. with a bostryx tendency. The first axes usually end in a, the last and sometimes the last but one in ?, fls. In the &, P 2, valvate, or 4, decussate, corolline; A ∞, free or not, the connective often elongated and the anthers variously shaped. In the 9, P 2-5; G usu. (2-3), with 2-3 loc., and axile plac. often projecting far into them; ovules ∞, anatr.; styles ± free. Ovary usu. winged; the wings persistent upon the capsular fr. No endosperm. Begoniaceae. Berberidopsis Hook. f. Flacourt. (1). (Berber., Lardizabal. auct.)

I Chili. Bot. Mag. t. 5343.

Berberis (Tourn.) L. Berberidaceae. 190 * S. Am. B. vulgaris L. (barberry) Brit. Shrubs. Two sections. In § 1, Mahonia (Nutt.), the l. are pinnate; many cult. shrubs. In § 2, Euberberis, the l. are simple, but usu. show a joint where the blade meets the petiole, seeming to indicate a derivation from a cpd. 1. There are also 'short' and 'long' shoots (cf. Conserae) in this §, to which B. vulgaris The latter have their l. met. into spines (usu. tripartite); transitions may often be seen. The former stand in the axils of the spines and bear green 1. and racemes of fls. (afterwards sometimes elongating to 'long' shoots). The pollination mechanism is interesting. The upper surface of the base of each sta, is sensitive to contact, and when it is touched by an insect in search of honey (secreted by the nectaries upon the bases of the inner P I.) the stasprings violently upwards, covering the side of the visitor's head with pollen, which it may place on the stigma in the next fir. visited. The fr. is sometimes made into preserves.

An interesting point about the common barberry is its connection with the disease known as black rust, which occurs on wheat and other Gramineae. The fungus (Puccinia graminis or Aecidium berberidis) passes through two alt. stages in its life history, one on the grass, the other on the barberry, so that if there are no barberry plants in a district, it is to a large extent, though by no means

absolutely, insured against black rust.

Beta (Tourn.) Linn. Chenopodiaceae (A). 6 sp. Eur., Medit.; I in
Brit., B. vulgaris L. or B. maritima L. the sea-beet, from which are derived the garden beetroot, the sugar-beet (var. Rapa Dumort.).

and the mangold-wurzel. The plant is a biennial and stores reserves in the root, the non-nitrogenous materials taking the form of sugar.

The sugar-beet is largely cult. in W. Eur. for its sugar, a formidable rival to the older industry of cane sugar. The sugar-contents of the roots have been continually improved by selection, and now frequently represent over 20%, of the weight. Germany grows 1½ million tons of beet sugar annually, and other countries about another 3 millions. [Herzog, Monographie der Zucker-rübe, Hamburg, 1899; v. Lippman, Geschichte der Rübe, Berlin, 1925.]

The garden beet is a favourite vegetable; the mangold is valuable for feeding cattle, &c. The l. are sometimes eaten like spinach.

Betula (Tourn.) L. Betulaceae (2). 38 N. temp., arct. B. alba L., the birch, is common in Brit. and reaches to the N. limit of trees, which is occupied by B. nana L., a creeping shrubby form, in much of the N. temp. zone. The winter buds are scaly, the scales representing stips.: the outer two or three pairs of them have no l. Witches' brooms are very commonly to be seen as dense tufts of twigs.

Trees with catkins of fls. The catkins are laid down in autumn as large buds at the end of the year's growth, the ? further back, on

B. alba. A, bract, bracteoles, and perianth, of δ , from within, with sta. removed; B, a stamen; C, floral diagram of A; D, bract, bracteoles and fls. of $\mathfrak P$ from within; E, the same with fls. removed; F, the same at ripeness of seed, G, floral diagram of D. b = bract; a, $\beta = \text{bracteoles}$ of fl. 1, or bracts of fls. 2, 3. After Eichler.

leafy branches. In the axil of each 1. of the catkin there are 3 fls. (cf. other genera of B.). The bracts of the lateral fls. occur (α, β) but no bracteoles. In the δ the bracteoles α β are joined to the bract itself. Each fl. has two sta. and a perianth, often reduced from the typical 4 1. to the 2 median 1., or even to the single anterior 1. The sta. are divided into halves nearly to the base; the lat. ones are absent. In the 3 the bracteoles α β are free from the bract at the time of fertilisation, but afterwards they unite with it to form the 3-lobed woody scale (F in figure) under the fruit (or rather the tissue

beneath them grows up, carrying up all together). The 2-loc. ovary gives rise to a 1-seeded nut, attached to the scale. No P. Tough wood, used for shoes, charcoal, &c. The oil from bark used in tanning Russia leather, to which it gives its fragrance. The bark of B. papriacea Ait. (N. Am.) used for making canoes.

Betulaceae (EP.; Cupuliferae p.p. BH.). Dicots. (Archichl. Fagales; pp. xiii, liv). 6/105, N. temp., trop. Mts., Andes, Arg. h with alt. undivided I. and membranous deciduous stips. Seedling stems radial in symmetry, but in old branches l. usu. 2 ranked, and facing upwards. Fls. monoec., anemoph., in term. catkins (or ? in heads); stem thus sympodial. In axils of catkin-l. are small dich. cymes, typically of 3 fls. (cf. Betula, &c.). Central fl. often absent, or some of the (typically) 6 bracteoles. & fl. united to br., l' or o, A 2-12; 2 with epig. P or o, G (2), 2-loc. at base, each with 1 pend. anatr. ov. with one integument; 2 free styles. Some chalazogamic. 1-seeded nut; endosp. o. After fert, br. and bracteoles grow into a scale- or

cup-like organ which may remain attached to fr. Classification and genera (after Winkler):

(Sympet. Tubiflorae; Personales, BH.). 100 gen., 800 sp. trop. One genus (Catalpa) common to old and new worlds. Most in Brazil; a few temp. Trees and shrubs, most commonly lianes, with opp. usu. cpd. exstip. 1. Many xero. shrubs with condensed stems, but the chief interest centies in the climbers, a very important feature in the forest veg. of S. Am. Twiners (e.g. Tecomaria, Pandorea), root-climbers (Ticoma radicans), and tendril climbers (most B.). In Eccremocarpus &c. the internodes and petioles are sensitive, but in most B. the tendrils are at the ends of the l. (in place of leaflets, as in Vicia). The tendrils are frequently branched; in some cases the branched tendril occupies the place of one leaflet. Three types of tendril are found—simple twiners, tendrils provided with adhesive discs (as in Virginia creeper), and hooked tendrils. See Glaziovia, Bignonia &c. The climbing stems exhibit many features of anatomical interest, owing to the peculiar growth in thickness.

Infl. usu. dich. with cincinnal tendency; bracts and bracteoles present. Fir. \S , +, hypog. K(5): C(5), usu. bell- or funnel-shaped, descendingly imbr.; A4, epipet., didynamous, the anther-lobes usu. one above the other, the post. std. always present; G (2) on hypog. disc, 2- (or rarely 1-) loc., with ∞ erect anatr. ov. on axile plac. Caps. septift. or loculic.: seed usu. flattened and with large membranous wing, exalb.

Classification and chief genera (after Schumann):

L. Bignonieas (ovary completely 2-loc., compressed || septum, or cylindrical; caps. septufr. with winged seeds; usu. tendrillate): Glaziovia, Bignonia, Oroxylum.

II. Tecomeae (ovary 2-loc., compressed \(\pm\$ septum or cylindrical; caps. loculic. with winged seeds; rarely tendrillate): Incar-

villea, Jacaranda, Catalpa, Tecoma, Spathodea.

III. Eccremocarpeae (ovary 1-loc.; caps. splits from below up.; seeds winged; tendrils): Eccremocarpus (only gen.).

IV. Crescentiese (ovary 1- or 2-loc.; fr. berry or dry indehiscent; seed not winged; usu. erect pl.): Parmentiera, Crescentia, Phyllarthron, Kigelia.

Borage, Borago officinalis L. (S. Eur., As. Minor.).

Boraginaceae (EP., BH.). Dicots. (Sympet. Tubiflorae; Polemoniales BH., pp. xlv, liii). 100/1800, trop. and temp., esp. Medit. Mostly herbs, often perenn. by fleshy r., rhiz., &c., a few h; sometimes climbing. L. usu. alt., exstip., usu., like rest of pl., covered with stout hairs (hence name Asperisolieae, by which B. sometimes known). Infl. usu. a coiled cincinnus, sometimes double, with marked dorsiventrality, uncoiling as fls. open, so that newly opened fls. face always in same direction. The morphology of this infl. is not fully clear; adnation or concrescence occurs, and possibly dichotomy

at apex. General agreement favours the view that the "boragoid," as it is sometimes called, is composed of dorsiventral monopodia. Cf. Nat. Pf., Muller in Flora, 94, Schuman, Morphol. Studien, II.

Fl. \$, usu. reg., hypog., usu. 5-merous; K (5), imbr. or open, rarely valv., odd sep. post; C (5), imbr. or conv., funnelshaped or tubular, limb usu. flat; A 5, epipet., alt. to pets., intr.; G (2), on hypog. disc, usu. 4-loc. (rarely 2- or 10-loc.) with "false" septum (cf. Labiatae), usu. with gynobasic entire or lobed style from base of ovary; ov. 1 in each loc., erect, ascending or horiz., anatr. Fr. of 4 achenes (nutlets), or drupe; seed with straight or

Floral diagram of Anchusa; after Eichler.

curved embryo in usu. slight endosp.; radicle directed upwards (cf. § V).

Most have a short tube, partly concealing the honey: many (esp. IV. I and 3) have scales projecting inwards from the throat of the C, concealing and protecting the honey, and narrowing the entrance, so that visiting insects must take a definite track. "Many sp. in the course of their individual development, seem to

recapitulate to us the evolution of their colours—white, rosy, blue in several sp. of Myosotis; yellow, bluish, violet in M. versicolor; and red, violet, blue in Pulmonaria, Echium, &c. Here, white and yellow seem to have been the primitive colours." (Müller.) Many B. are heterostyled, e.g. Pulmonaria. The fis. of many sp. are pendulous (and thus bee-flowers), e.g. Borago, Symphytum. Echium is gynodiœcious.

Classification and chief genera (after Gurke):

CORDIOIDEAE (drupe; style terminal: twice bilobed): Cordia.

EHRETIOIDEAE (do.; style simple or bi-lobed or II. double; no ring of hairs): Ehretia.

HELIOTROPIOIDEAE (do., do., but ring of hairs near III. tip of style): Tournefortia, Heliotropium.

IV. BORAGINOIDEAE (style gynobasic: achenes).

I. Cynoglosseae (fl. reg.; base of style more or less conical: tips of achenes not projecting above pt. of attachment): Omphalodes, Cynoglossum, Rindera.

Eritrichieae (do., but tips projecting above pt. of attachment): Echinospermum, Eritrichium, Cryptanthe.

3. Anchuseae (fl. reg.; base of style flat or slightly convex; achenes with concave attachment surface): Symphytum, Borago, Anchusa, Alkanna, Pulmonaria.

Lithospermeae (do., but surface of attachment flat): Myo

sotis, Lithospermum, Arnebia, Cerinthe.

Echieae (fl. zygomorphic): Echium.

V. WELLSTEDIOIDEAE (4-merous; ov. compressed, 2-loc. with one pend. ov. in each; caps.): Wellstedia.

Boragineae (BH.) = Boraginaceae.

Boraginodes Post et O. Ktzc. (Trichodesma p.p.). Borag. (IV. 1). ı Somalıland.

Borago L. Boraginaceae (IV. 3). 3 Medit., Eur., As. B. officinalis L. Brit. (borage) cult. for bee feeding. It has a typical bee-fl. The blue pendulous fl. secretes honey below the ovary; the clastic sta. form a cone and dehisce introrsely from apex to base, the pollen ripening gradually and trickling into the tip of the cone. Insects probing for honey dislocate the sta., receiving a shower of pollen (cf. Erica, Galanthus, Cyclamen). In older fls. the stigma, now ripe. projects beyond the sta. so as to be touched first.

Boragoid, Boraginaceae.

Borassodendron Becc. Palmae (11). 1 Perak.

Borassus L. Palmae (11). 4 palaeotrop. B. flabellifer L. (Palmyra palm) cult. in Ceylon, India, &c. Dioecious. Its uses are legion; an old Tamil song enumerates 80r. The wood of the trunk is very hard and durable, and resists salt water; it is also used for rafters. well-sweeps, &c. The large fanshaped 1. are used as thatch, and made into olas or writing "paper" sheets, the writing being done upon them with a stylus. From the base of the l. Palmyra fibre is collected, and used for making brushes, &c. The split l. are woven into mats, baskets, &c. The fr. is eaten roasted, and the infl. is tapped for toddy (cf. Cocos, Agave) from which sugar or jaggery is made, as well as vinegar, &c. The young seedlings are also eaten and yield a good flour when ground, and there are many other uses.

Brake, Pteridium aquilinum (L.) Kuhn; curled rock-, Cryptogramme crispa R. Br.

Bramble, Rubus.

Branch, an outgrowth of r. or shoot which repeats its structure; usu. lat. (not dichotomous), exogenous in case of shoot, endogenous in r. In many ferns the branches are on the l. bases, but in Equisetum and fl. plants are usu. axillary. Usu. only one in each axil; if more than one, the others are accessory: if side by side, collateral, Allium, Araceae, Crataegus, Liliaceae, Muscari, Quercus, Salix; if one above the other, serial, Aristolochia, Calycanthus, Cercis, Colletia, Fuchsia, Gleditschia, Robinia, Syringa. Branches of two kinds—long and short shoots, or shoots of unlimited and limited growth-occur in Pinus and other Coniferae, Berberis, Cactaceae, Ginkgo, Spergula.

Branching may be of two types-monopodial, Pinus and other Coniferae, Orchidaceae, Paris, Pothos, or sympodial, Acorus, Aglaonema, Ancistrocladus, Anonaceae, Anthurium, Araceae, Asarum, Eichhornia, Fagus, Íridaceae, Iris, Juncus, Liliaceae, Narthecium, Orchidaceae, Peperomia, Pistia, Polygonatum, Pontederiaceae, Potamogelon, Ranunculus, Rhaphidophora, Ulmaceae, Vitis, Zostera.

And of. Buds, Concrescence, &c.

Brassia R. Br. Orchidaceae (II. 19). 30 trop. Am.

Brassica (Tourn.) L. (BH. incl. Erucastrum Presl and Sinapis L.). Cruciserae (2). 35 Eur., Medit., As. 7 in Brit. Many forms are cult., some for the fir., others for the stem, root, leaf, or seed. B. nigra Koch is the black mustard, whose seeds yield the condiment. B. oleracea L. is the cabbage, with the various races derived from it, such as cauliflower and broccoli (fleshy infl), kale or curly greens or borecole, brussels-sprouts (a form in which miniature cabbages are produced in all the leaf-axils on the main stem), kohl-rabi or knolkohl (trop.) (a thickened stem, or corm, showing leaf scars on its surface), &c. B. campestris L. is the turnip, a biennial with thickened root, and a var. of it—B. Napus L.—is the rape, used in salads and in the preparation of tape- or colza-oil, expressed from the seeds. [See De Candolle's Orig. of Cultiv. Plts.] It is of interest to notice the great variety of morphology in the veg. organs, correlated with the different ways in which storage of reserve materials is effected, in the root, stem, leaf, flowerstalk, &c.

Sauer-kraut, or salted cabbage, made by packing cabbage shreds in barrels with salt and pepper, and slightly fermenting, is a favourite

food in Germany, esp. for winter use.

The outer coat of the seed has mucilaginous cell-walls which swell when wetted (cf. Linum).

Brassocattleya × Rolfe. Hybrid, Brassavola × Cattleya; others are Brassolaelia, Brassoepidendrum, Brassocattlaelia (triple).

Some with Bromeliaceae (EP., BH.). Monocots. (Farinosae; Epigynae BH.: pp. vii, liv). 65/850, trop. Am., W.I. Many terrestrial (xero., on rocks. &c.), but most epiph. by virtue of seed distr. and xero. habit, and more char. of trop. Am. than the orchids. Stem usu. reduced, with rosette of fleshy l. channelled above, fitting closely at base, so that the whole pl. forms a kind of funnel, usu. full of water. In this

are dead 1., decaying animal matter, and other debris (certain Utricularias live only in these pitchers). There are many adv. r.

which fasten the plant to its support, but which do not aid in its nutrition, or very little. The bases of the l. are covered with scaly hairs by which the water in the pitcher is absorbed. Water is stored in the 1., which consist largely of water-tissue. They have a thick cuticle and often bear scaly hairs that reduce transpiration. Some show a totally different habit to this, e.g. Tellandsia usneoides (q.v.). [See Schimper, Epiph. Veg. Amerikas.]

Infl. usu. out of the centre of the pitcher; bracts coloured. Fl. usu. ?, reg., 3-merous. $P_3 + 3$ or (3) + (3), the outer whorl sepaloid, persistent, the inner petaloid; A 6, introrse, often epipet.; G (3), inf., semi-inf., or sup., 3-loc., with ∞ anatr. ov. on the axile plac. in each. Style 1, stigmas 3. Berry or caps.; seeds in the latter case very light, or winged. Embryo small, in mealy endosp.

Classification and chief genera (after Wittmack):

Tillandsieae (caps.; ov. sup.; l. entire; seed hairy): Tillandsia.

- Puyeae (caps.; ov. sup.; l. thorny; usu. large stem): Puya, Dvckia.
- 3. Pitcairnieae (caps.; ov. semi-inf. or almost sup.; l. entire, or toothed at base, rarely at top); Pitcairnia.

4. Bromelieae (berry; ovary inf.; l. with thorny teeth): Bro-

melia, Ananas, Billbergia, Aechmea.

Bromheadia Lindl. Orchidaceae (II. 5). 6 Malaya.

Brosimopsis Sp. Moore. Moraceae (II). I Matto Grosso.

Brosimum Sw. Moraceae (11). 10 trop. and S. temp. Am. Infl. remarkable, a spherical pseudo-head composed of one ? fl. and many & fls. The former is sunk into the centre of the common recept. and its style projects at the top, whilst the latter occupy the whole of the outer surface. Each of fl. has a rudim. P. and one sta., whose versatile anther in dehiseing passes from a shape somewhat like = to one like . Achene embedded in the fleshy recept.

The achene of B. Alicastrum Sw. is the bread-nut (not to be confused with Artocarpus, the bread-fruit), which is cooked and eaten in the W.I., &c. [The bread-nut of Barbados is, however, a seeded var. of the bread-fruit.] B. Galactodendron D. Don is the cow-tree or milk-tree of Venezuela. The milky latex flows in considerable quantities, tastes very like ordinary milk, and is used for the same

purposes. The wood of several sp. is useful (snake-wood).

Burn-nose (W.I.), Daphnopsis.

Burragea Donn. Smith et Rose (Gaura p.p.). Onagr. (2). 2 Lower Calif.

Burrielia DC. Compositae (6). 1 Calif.

Bursa Weber in Wigg. = Capsella Medic. (Crucif.).

Bursaria Cav. Pittosporaceae. 3 Austr. Seeds few in fr.

Bursera 'Jacq.' ex L. Burseraceae. 45 trop. Am. B. gummifera L. (birch tree, gommier, turpentine tree) furnishes the balsam resin known

as American elemi, chibou, cachibou, or gomart.

Burseraceae (EP., BH.). Dicots. (Archichl. Geraniales EP., BH.). 13 gen., 350 sp., trop. Shrubs and trees with alt., usu. cpd., dotted 1. Balsams and resins occur, in lysigenous or schizogenous passages. Fls. small, generally unisex., with disc like Rutaceae, 5- or 4-merous. obdiplost, when both whorls of sta. are present. Cpls. (5-3), ov. usu. 2 in each. Ovary multiloc. with one style. Drupe or caps. Seed exalb. Many of the order are useful on account of their resins. &c. Chief genera: Commiphora, Boswellia, Bursera, Canarium.

Burtonia R. Br. Leguminosae (III. 2). 10 Austr.

Buseria Th. Dur. (Leiochilus EP.). Rubiaceae (11. 4). 1 Madag.

Bush (Austr.), scrub, cf. Acacia; -clover, Lespedeza.

Bush-wood, a forest in which the shrubs are so abundant as to keep the crowns of the trees from touching.

Bushiola Nieuwland (Kochia p.p.). Chenopod. (A). I N. Am.

Busses Harms. Leguminosae (11. 7). 1 E. trop. Afr.

Bustelma Fourn. Asclepiadaceae (11. 1). 1 Brazil.

Butayea Wildem. (Pseudoblepharis EP.). Acanth. (IV. B). I Congo.

Butcher's broom, Ruscus aculeatus L.

Butea Koen. ex Roxb. Leguminosae (III. 10). 4 Ind., China. frondosa Roxb. (dhak or palas tree, or bastard teak), one of the handsomest of fig. trees. A red juice flows from incisions in the bark; when dried it is known as Bengal kino and used as an astringent. The fls. yield a fugitive orange-red dye. The tree also yields lac (see Ficus), and is very important for lac cult.

Butomaceae (EP.; Alismaceae p.p. BH.). Monocots. (Helobieae). 4 gen., 7 sp., trop. and temp. Water and marsh herbs with 1. of various types. Infl. usu. a cymose umbel. Flr. \$, reg., 2- or 3-merous, hypog. P 6, in two whorls, the outer sepaloid, the inner petaloid (exc. Butomus). Sta. $9-\infty$, with introrse anthers. Cpls. $6-\infty$, apocp., with ∞ anatr. ov. scattered over their inner walls (cf. Nymphaea), except on midrib and edges. Follicles; seed ex-alb.; embryo straight or horse-shoe shaped. Chief genera: Butomus, Hydrocleis.

Butomopsis Kunth (Tenagocharis EP.). Butomaceae. I Austr. Butomus L. Butom. I temp. As., Eur. (incl. Brit.), B. umbellatus L. (flowering rush). Intl. a term. fl. surrounded by 3 bostryxcymes.

Butonica Lam. = Barringtonia Forst. p.p. (Lecyth.).

Butter, cf. oils; -bean, Phaseolus vulgaris L.; -bur, Petasites officinalis Moench.; -and eggs (Am), Linaria; -cup, Ranunculus; -nut, Caryocar, (Am.) Juglans; shea-, Butyrospermum; -tree, Pentadesma, Bassia; -wort, Pinguicula.

Butterfly flowers (class F), Cuphea, Daphne, Eupatorium, Gentiana. Lonicera, Lychnis, Onagraceae, Rubiaceae, &c.; -orchis, Habenaria,

Oncidium.

Button-bush (Am.), Cephalanthus: -tree, (W.I.), Conocarpus; -weed (W.I.), Spermacoce, Borreria; -wood, Platanus occidentalis.

Buttonia MacKen. Scrophulariaceae (III. 2). 2 S. and trop. Afr.

Butus Eichl. = Abuta Aubl. p.p. (Menisperm.).

Butyrospermum Kotschy. Sapotaceae (1). 2 trop. Afr. The oily seeds of B. Parkii Kotschy when pressed yield shea butter.

Buxaceae (EP.; Euphorbiaceae p.p. BH.). Dicots. (Archichl. Sapindales). 6 gen., 30 sp. temp. and trop. Evergreen shrubs with exstip. leathery l., and no latex. Fls. in heads or spikes, unisex., reg., apet. or naked. Sta. 4-0. G usu. (3), 3-loc., with 3 styles which are persistent on the fr. Ov. 2-1 in each loc., pend., anat., with dorsal raphe. Loculic. caps., or drupe. Seed with caruncle or none. Endosp. Chief genera: Buxus, Pachysandra.

Buxanthus Van Tieghem (Buxus p.p.). Buxaceae. 2 trop. Afr.

Buxella Van Tieghem (Buxus p.p.). Buxaceae. 2 S. Afr., Madag. Buxus L. Buxaceae. 25 palaeotemp., W.I. B. Sempervirens L. (box) often cult. Fls. in heads, a term. ? flr. surrounded by a number of a fls. The fr. dehisces explosively, the inner layer of the pericarp separating from the outer and shooting out the seeds by folding into

a U-shape (cf. Viola). The wood of box (q.v.) is exceedingly firm and close-grained, and is largely used in turning, wood-engraving, &c. Byblis Salisb. Lentibulariaceae (usually in Droseraceae, but cf. Lang in Flora 88, p. 179). 2 Austr. Insectivorous undershrubs, with stalked and sessile glands like Pinguicula. Byronia Endl. (Ilex p.p.). Cactaceae (EP., BH.). Dicots. (Archichl. Opuntiales; Ficoidales BH.).
25 gen., 1500 sp., chiefly localised in the dry regions of trop. Am., but spreading to a distance N. and S. (Opuntia missouriensis as far as 59° N.), and far up the mountains (to 12,000 ft. and even higher).
Even in the damp forest regions some sp. appear as epiphytes. The only representative of the order in the Old World is Khipsalis, found in Afr., Mauritius, &c., but several sp. of Opuntia, &c. are now nat. in S. Afr., Austr., &c. and becoming troublesome.

Xero. of the most pronounced type, exhibiting reduction of the transpiring surface, and also storage of water, often in great quantity. The veg. organs show great var. of type; the classification is perhaps better based upon them than upon the repr. organs. R. generally long and well-developed (in cultivation liable to decay). Stem

fleshy, of various shapes, rarely bearing green l., and usu, provided with sharp barbed thorns, which give protection against animals. We may consider briefly some of the more important types of shoot found in C. (refer to genera for further details). The nearest approach to the ordinary plant-type is perhaps Pereskia, which has large green 1., somewhat fleshy, in whose axils are groups of thorns mixed with hairs; the space occupied by these is termed the arcole. About the morphology of the spines there has been much dispute; most authors regard them as repres. the l. of the axillary shoot, whose stem is undeveloped, but there is also good evidence in favour of the view that they are "emergences." In some gen, they are provided with The next stage is found in Opuntia, where the stem has taken over the water-storing and assim. functions, but still bears l.; in some sp. these aid the stem functions throughout life, but in most they fall off very early, and the stem is usually flattened to expose more surface to air and light. Then we come to Leuchtenbergia, which has an aloe-like habit with the areoles on the tips of the apparent 1.; the fl. arises either in the axil of the "leaf" or on the areole. Development shows that the apparent I, is really a cod. structure. The bud stands, not exactly in the axil, but on the base of the l., and the two grow out together to form a leaf-cushion or mammilla, at the outer end of which is the growing point and the rest of the l. itself; the latter is represented by a small scale (often microscopic) and the former gives rise to the thorns, &c. on the arcole. The same phenomenon is seen in Mammillaria, Cereus sp., &c. In some cases the growing point divides, during the growth of the mammilla, into two, one on the tip, the other in the axil, of the The latter gives rise to the fl. In Cereus, Echinocactus, &c. the stem is ± cylindrical, bearing ribs on which are the areoles at regular intervals; the rib is formed by the "fusion" of mammillae. i.e. by the growth of the tissue under them during their development (cf. formation of sympetalous corolla). In Phyllocactus, Epiphyllum, and sp. of Rhipsalis some or all of the shoots exhibit a flattened leafy form with areoles in notches on their edges. This form appears to be. derived from the preceding by abortion of some of the ridges, and reversions are often seen (they appear if access of light be prevented). Lastly, other sp. of Rhipsalis show perfectly cylindrical stems.

The bulk of the internal tissue consists of parenchyma in which water is stored; the cell-sap is commonly mucilaginous, thus further obstructing evaporation. The cuticle is thick, and the ridges of the stem are usu. occupied by mechanical tissue, whilst the stomata are in the furrows. Everything thus goes to check transpiration to the utmost extent; it is very difficult to dry a cactus for the herbatium, and its vitality is very great. Its growth is slow, but sp. of Cereus, &c. reach a great size. Veg. repr. is frequent in the mammillate forms, and occurs to some extent in others. In garden practice, cacti are often multiplied by cuttings, for a piece cut off and stuck into the soil will usually grow. Grafting is also largely resorted to.

Fls. usu. solitary (exc. Pereskia), borne upon or near the areoles or in the axils of mammillae, large, brightly coloured, ξ , reg. or +. P (∞), showing gradual transition from sepaloid to petaloid 1., spirally

arranged, often up the side of the ovary (cf. Nymphaea). Sta. ... epipet. G (4-∞), uniloc. with parietal plac. and ∞ anatr. ov.; style simple. Berry, the flesh derived from the funicles. Endosp. or none.

The fr. of many sp. is edible (e.g. Opuntia, &c.). Several are used in making hedges. Cochineal is cultivated on Nopalea, Opuntia, &c.

Classification and chief genera (after K. Schumann):
I. PERESKIOIDEAE (habit of ordinary pl., with flat 1. and panicles; no barbed thorns): Pereskia (only genus).

OPUNTIOIDEAE (succulents with round or flat leaf-like joints; I. cylindrical, usu. falling very early; barbed thorns; fl. rotate): Opuntia, Nopalea (only genera).

III. CEREOIDEAE (succulents; l. reduced to scales, often

very minute; no batbed thorns):

Echinocacteae (fl. funnel- or salver-shaped, in or near the areole): Cereus, Phyllocactus, Epiphyllum, Echinocactus, Melocactus, Leuchtenbergia.

Mammillarieae (do., but in axil of mammilla): Mammil-

laria, Pelecyphora.

Rhipsalidene (fl. rotate) : Rhipsalis.

Cf. genera. Also Britton and Rose, Cactaceae, Nat. Pfl., and ed., Goebel, Pflanzenb. Sch. and in Flora 1895, Ganong in Ann. Bot 1898, Schumann in Nat. Pfl. and Gesammtbeschreibung der Kakteen, 1807-00, and Vochting in Pringsh. Jahrb. 1804. Cf. also Euphorbia and Stapelia.

campanula (Tourn.) L. Campanulaceae (1. 1). 300 N. temp. and trop. Mts., esp. Medit.; 8 Brit. incl. C. rotundifolia L. (harebell blue-bell of Scotland). The pollen is shed in the bud, the sta. standing closely round the style and depositing their pollen upon the hairs. As the fl. opens the sta. wither, exc. the triangular bases that protect the honey, and the style presents the pollen to insects. After a time the stigmas separate and the fl. is ?; finally the stigmas curl right back on themselves and effect self-pollin. (See fam. and cf. Phyteuma, Jasione.) Seeds light and contained in a caps., which if erect dehisces at the apex, if pend. at the base, so that the seeds (cf. Aconitum) can only escape when the plant is shaken, eg. in strong winds. Several are cult. (Canterbury bells, &c.).

Campanulaceae (EP, BH.). Dicots. (Symp. Campanulatae). 60 gen. 1000 sp., temp. and sub-trop., mostly perennial herbs (a few trees and shrubs), with alt., exstip. I., and usu. with latex. The infl. may term, the primary axis, or one of the second order. It is generally racemose, ending with a term, fl. in Campanuloideae. In some cases, instead of single fls. in the axils of the bracts of the raceme, small dich. occur (cf. Labiatae). Others have the whole infl. cymose

(Canarina, Pentaphragma, &c.).

Fl. usu. orall, reg. or lart, epig., generally 5-merous, the odd sepal postin Campanuloideae, but anterior in the other groups. In these, however, a twisting of the axis through 180° takes place before the fl. opens (cf. Orchids), so that the odd sepal is finally post. K 5, open; C (5) valvate; A 5 epig.; anthers intr., sometimes united; \overline{G} (5), (3) or (2), multi-loc. with axile place bearing ∞ anatr. ov. Style simple; stigmas as many as cpls C aps. dehise. in various ways in different

gen., or berry. Fleshy endosp.

The nat. history of the fl. is of interest, both in itself and as exhibiting transitions to the Composite type. Honey is secreted by a disc at base of style and covered in most cases by the triangular bases of the sta., which fit closely together and only allow of the insertion of a proboscis between them. This, taken together with the size of the fls., their frequently blue colour and pendulous position, points to their being best adapted to the visit of bees, as is the case, but there are also many other visitors of various insect classes, so that this fam. cannot be placed in the fl. class H but must go into B. A few exceptions occur; the bulk of the fam. has large fls., conspicuous by themselves, but Phyteuma and Jasione have small fls. massed in heads, and come into class B' along with the Compositae.

The general principle of the fl. mech. is the same throughout, and agrees with that of Compositae. The fl. is very protandr., and the

style (with the stigmas closed up against one another) has the pollen

shed upon it by the anthers, either in the bud or later. Usu, there is a bunch of hairs upon the style to hold the pollen. For some time the style acts as pollen-presenter to insects; after a time the stigmas separate and the ? stage sets in, and finally, in many cases, the stigmas curl back so far that they touch the pollen still clinging to their own style, and thus effect self-pollin. See genera, esp. Campanula, Phyteuma, Jasione, Lobelia, and cf. Compositae.

Canker-berry (W. I.), Solanum bahamense L.

Canna L. Cannaceae. 60 trop. and subtrop. Am., C. indica L. cosmop. trop. Many sp., vars. and hybrids, cult. C. indica (Indian shot) is the basis of most of these. Habit like Zingiberaceae or Marantaceae, but C. can be distinguished even when not in fl. by

possessing neither the ligule of the former nor the pulvinus of the latter. Infl. term. usu. composed of 2-fl. cincinni. The two fls. are homodromous, but the bracteole is to the right in one and to the left in the other (behind one or other of the two lat. sepals in the diagram). Fl &, asymmetric, epig. K 3. C (3). The A is the most conspicuous part. There is a leafy sta. bearing half an anther on one edge, and a number of petaloid structures round it, usu. 3 but sometimes 1 or 4. One of these is the labellum (not = that of Zingiberaceae), and is rolled back on itself outwards. The other two are often termed the wings (a β in diagram). When a fourth std. $(\gamma, cf.)$ Marantaceae) is present it stands behind the fertile sta. Other sp. have only the labellum. style, 3-loc.; ov. in 2 rows in each loc., anatr. Caps., usu. warty. Seed with perisperm and straight embryo.

Floral diagram of Canna indica (after Eichler). The bracteole is omitted. S = petaloid style; L=labellum; aß = staminodes.

G (3) with petaloid

As to the morphological explanation of the A, there are two views

Eichler (Blütendiag. I. p. 174) regards the labellum as a lat. sta. of the inner whorl, and the fertile sta. together with all the stds. as the post. sta. of the same whorl; the other sta. of the inner, and all the sta. of the outer, whorl are wanting. The older view looks upon β , γ , as the 2 post. sta. of the outer whorl, and the labellum, α , and the fertile sta. as the 3 sta. of the inner whorl. (Cf. this fl. with those of Musaceae, Zingiberaceae and Marantaceae.)

The pollen is shed upon the style in the bud; insects alight on the labellum, touch first the term, stigma and then the pollen. The

rhiz. of C. edulis Ker-Gawl. is ed., containing much starch.

Cannabaceae, Cannabinaceae = \S IV. of Moraceae (q.v.).

Cannabis (Tourn.) L. Moraceae (IV). 1 Cent. As., C. sativa I., the hemp. Infl. like Humulus &, dioec. Hemp is largely cult. both in temp. and trop. regions, in the former for the fibre, in the latter for the drug. A valuable fibre, used for ropes and other purposes, is obtained from the inner bark of the stem, much as flax is prepared from Linum, and for this purpose the plant is cult. in S. Eur., the eastern U.S., and other countries. In the trop., and esp. in India, the pl. is cult. for the sake of the narcotic resin which exudes from it, and which is used much like opium, both as a drug and as a stimulant. The drug occurs in three common forms, ganja, charas, and bhang. The first is the ? fig. tops with resin on them, packed together, the second, which comes from rather cooler climates, is the resin knocked off the twigs, bark, &c., and the third, which is largely obtained from the wild plants, is the mature l., with their resinous deposit, packed together. Asiatics are much addicted to the use of hemp as a narcotic. It is smoked, with or without tobacco, and an intoxicating liquor, hashish, is made from it. The resin has an intoxicating stimulating effect. In small quantities it produces pleasant excitement, passing into delirium and catalepsy if the quantity be increased. The names given to the plant among them indicate this use of it, e.g. leaf of delusion, increaser of pleasure, cementer of friendship. The sale of ganja and charas is kept in check in India by a stringent licensing system, but that of bhang, which is collected from wild plants, is hard to control. Cf. Literature (Watt). Capnorea Rasin. (Hesperochiron S. Wats.). Hydrophyll. 18 P. c., N. Am. Cappardaceae (EP., BH.). Dicots (Archichl. Rhoeadales; Parietales BH.). 40 gen., 450 sp., ttop. and warm temp., many xero., with reduced, osten inrolled, l. (cl. Empetrum). Herbs or shrubs, with alt. simple or palmate l., osten with stips. (frequently repres. by thorns or glands). Fls. ₹, reg., usu. in racemes, bracteate but without bracteoles. The P resembles that of Cruciserae (K2+2, C4 diagonal), but great var. occurs in the A. In some sp. of Cleome there are 4 sta. in two whorls, but elsewhere there are more. Some sp. of Cleome, &c. show tetradynamous sta. In others, still further branching of the median sta. occurs and usu. the post. sta. is more branched than the ant. Staminody of some of the branches is frequent. Cpls. typically (2), transv. as in Cruciserae, with parietal plac. In many sp. of sub-order II the number rises to 10 or 12 by the addition of a second whorl of cpls. and by dédoublement. Ovules ∞, campylotropous.

A further complication is the presence of axial effigurations, &c. in the fls. A disc may occur between P and sta. (usually thicker at the post. side), or a gynophore between sta. and ov., or both. Or the disc may grow up in the centre to form an androphore on which the sta. are borne and above them there may be a gynophore also. From the disc there often grow out structures of various shapes and sizes; these may be scales quite free from one another, or, as in Cadaba, &c., may be united into a tube. Or the scales may, as in

Steriphoma, &c., alt. with and be joined to the sepals.

Fr. a siliqua (with replum), nut, berry or drupe. Seed exalb. with embryo folded in various ways as in Cruciferae. Few are useful: see Capparis. &c.

Classification and chief genera (after Pax):

A. Mostly shrubs, with hairs or scales, rarely glandular. No replum.

I. DIPTER YGIOIDEAE (samara): Dipterygium.

II. CAPPARIDOIDEAE (berry): Capparis, Cadaba, Maerua, Koeberlinia.

III. ROYDSIOIDEAE (drupe): Roydsia.

IV. EMBLINGIOIDEAE (prostrate undershrubs; calyx-tube present; C (2); nut): Emblingia (only

B. Glandular annuals; siliqua with replum. [genus].

V. CLEOMOIDEAE: Cleome, Polanisia.

Carvalhoa K. Schum. Apocynaceae (II. I). 2 E. trop. Afr.

Carya Nutt. Juglandaceae. 12 E. N. Am., the hickory trees, cultivated for their wood, which is very tough and elastic, and for the edible fruit (pecans, like walnuts).

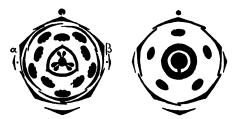

Caryocar Lunn. Caryocaraceae. 15 sp. ttop. Am. The wood is very durable and is used in ship-building. The fruit is a large 4-stoned drupe; the seeds are the Souari- or Butter-nuts of commerce.

Caryocaraceae (Rhizoboleae) (E.P.; Ternstroemiaceae p.p. BH.). Dicots. (Archichl. Parietales). 2 gen., 15 sp. trop. Am. Trees and shrubs with ternate opp. or alt. I. with deciduous stips. Fls v in racemes. K (5−6), C (5−6), A∞, united into a ring or in 5 bundles. G 4-or 8−20-loc. with as many styles. 1 pend. ov. per loc. Usu. drupe with oily mesocarp, and woody endocarp which splits into 4 mericarps; sometimes a leathery schizocarp. Little or no endosp. Genera: Anthodiscus, Caryocar.

Caryodendron Karst. Euphorbiaceae (A. II. 2). 2 trop S. Am.

Caryophyllaceae (EP.; BH. excl. Illeebraceae or Paronychiaceae, and Scleranthaceae). Dicots. (Archichl. Centrospermae). 80 gen., 1300 sp. cosmop (many Brit.), mostly herbs, a few undershrubs, with opp. simple usu entire l_* , often stip.; the stem often swollen at the nodes, the branching dich. The infl. usu. term. the main axis and is typically a dich. cyme, but both in the veg. region and in the infl., of the two branches arising at any node, one (that in the axil of β) tends to outgrow the other and after two or three branchings the weaker one often does not develope at all, so that a cincinnus arises. The whole infl. is very char, and such an one is often called a caryophyllaceous infl.

Fls. $\mathfrak P$ and reg., but often not isomerous. As a type, the formula of Lychnis may serve: K (5), C 5, A 5 + 5, G (5), with free central plac., uniloc. Ov. usu. ∞ , in double rows corresponding to the

Floral diagrams of (1) Silene in flata and (2) Paronychia sp. (after Eichler), showing the ordinary type of fl. in Silenoideae and the most reduced type of Alsinoideae; a, β = bracteoles.

cpls., rarely few or 1 (Paronychieae), usu. campylotropous. In most cases the fl. is obdiplost. as may be recognised by the cpls. (when 5) being opp. the petals. Frequently, reduction of the number of parts occurs, e.g. G (3) or (2) or rarely (4); A 4+4, or 5, 3, 2, or 1, and in other cases the C may abort (Sagina sp., Herniaria, &c.). The overy, sta., and corolla are sometimes borne on an androphore

(e.g. Lychnis), an elongation of the axis between K and C. The petals sometimes have a ligule (e.g. Lychnis), and are often bifid. At the base of the ovary are often seen traces of the septa, which in the upper part do not develope; in some cases the plac. is basal.

Biologically, as well as morphologically, the fam. forms two distinct groups, a higher type, the Silenoideae, and a lower, the Alsinoideae. All secrete honey at the base of the sta., but while in the A. the fl. is wide open, so that short-tongued insects can reach the honey, in the S. a tube is formed by the gamosepalous K; in this stand the claws of the petals and the sta., partly filling it up, and rendering the honey inaccessible to any but long-tongued insects, esp. bees and Lepidoptera. The latter class, esp. in the Alps (see Müller's Alpenblumen), are the chief visitors, and many of the S. are adapted to them—by length of tube, red and white colours, night-flowering in many sp., or emission of scent only at night, &c. The fls. are commonly protandr. Many A. are gynodioec. (cf. Labiatae).

Fr. usu. a caps. containing several or ∞ seeds. It opens in nearly all cases by splitting from the apex into teeth which bend outwards, leaving an opening. The splitting may take place in as many, or in twice as many, lines as cpls. The seeds cannot escape from the capsule unless it be shaken, e.g. by wind or animals, and being small and light have a good chance of distr. Embryo usu. curved round the

perisperm (in a few cases nearly straight).

Classification and chief genera (after Pax):

I. ALSINOIDEAE (fir. polysepalous; sta. often perig.).

a. Fruit a capsule opening by teeth.

Alsineae (styles free to base; l. exstip.): Stellaria, Cerastium, Sagina, Arenaria.

Sperguleae (do., but l. stip.): Spergula, Spergularia.
 Polycarpeae (styles joined at base): Drymaria, Polycarpon.

- b. Fruit an achene or nut.
 - 4. Paronychicae (fls. all alike; stipules): Corrigiola, Paronychia, Illecebrum, Herniaria.

Dysphanieae (do., but l. exstip. alt.): Dysphania.
 Sclerantheae (do., exstip. opp): Scleranthus.

7. Pterantheae (fls. in 3's, the 1 lat. ± abortive): Pteranthus. II. SILENOIDEAE (fl. gamosepalous, hypog.):

Lychnideae (calyx with commissural ribs): Silene, Lychnis.
 Diantheae (no commissural ribs): Gypsophila, Dianthus.

BH. separate off groups I, 4—7 as an independent fam. Illecebraceae (Monochlam. Curvembryae), retaining the rest (Caryophylleae) in Polypetalae Caryophyllinae. This is an unnatural separation of closely allied groups. See discussion of relationships of these fams. in Nat. Pfl. (Caryophyllaceae, p. 68).

Cassia Tourn. ex L. Leguminosae (11. 5). 400 trop. and warm temp. (exc. Eur.). Trees, shrubs and herbs with paripinnate l. and stips. of various types. Fl. ., but with petals almost equal in size. The sta. may be 10, but the 3 upper ones are usu. reduced to stds. or The anthers usu. open by pores. The 5 upper sta. are generally short, the 2 lower are long and project outwards. In many two forms of fl. occur, one in which the lower sta. project to the left, the other in which they project to the right. It was once thought that this enantiostyly was a kind of heterostylism, but both types of fl. occur on one plant. It would appear to be simply a case of variation in symmetry (cf. Exacum, Saintpaulia). In many sp. a division of labour takes place among the sta. (cf. Heeria); the insect visitors eat the pollen of the short sta. and carry away on their bodies that of the long. There is no honey. Fr. often chambered up by 'false' septa running across it—outgrowths from the placenta.

Many cult. for the 1., which when dried form the drug senna. Alexandrian senna from C. acutifolia Delile, Italian C. obovata Collad., Arabian C. angustifolia Vahl. C. Fistula L. (purging Cassia, pudding-pipe tree) has its seeds embedded in laxative pulp.

Cassia bark, Cinnamomum Cassia Blume; -broom, Cassia.

Castor oil, Ricinus communis L.

Castratella Naud. Metastomaceae (1). 1 Colombia.

Casual, an occasional weed of cultivation, not naturalised.

Casuarina Linn. Casuarinaceae. 35 Austr., Polynes., &c. Trees, often of weeping habit, with long slender green branches, cylindrical and deeplygrooved. At the nodes are borne whorls of scale! like those of Equisetum. The stomata and green tissue are at the bases of the grooves, whilst the ridges are formed of sclerenchyma, so that the plant is markedly xero. Fls. unisex. The & are borne in term. spikes on short lat. branches. The internodes are short and at every node is a cup (formed of the combined bracts) with several sta. hanging out over the edge. Each repres. a & fl. and has a 2-leaved P and 2 bracteoles. The ? fls. are borne in dense spherical heads. Each is naked in the axil of a bract, has 2 bracteoles, and consists of 2 cpls., syncp., the post. loc. empty, the ant. containing 2 or more ov. The long styles hang out beyond the bracts and wind-fert.

occurs. Afterwards the whole head becomes woody (bracts as well) enclosing the ripening seeds. The seed is winged and is enclosed in the woody bracteoles. Exalb. Wood (beef-wood) valued for hardness; several sp. are used, known in Austr. as she-oak, forest-oak,

&c. The green shoots are used as fodder for cattle.

Casuarinaceae (EP., BH.). Dicots. (Archichl. Verticil.; Unisexuales BH.). Only genus Casuarina (q.v.). The place to be assigned to this fam. in the natural system has been much disputed. Its nearest allies seem to be Betulaceae. In 1891 Treub discovered the chalazogamic fert. (cf. Chalazogamae) and proposed to remove it from its place near the B. Later discoveries however show that these pl. too are chalazogamic, as also Juglans, and thus C. may still be kept beside

Cocropia L. Moraceae (III). 45 trop. Am. Trees of rapid growth. with very light wood, used for floats, &c. Infl. a very complex cyme (see Bot. Centr. 57, p. 6). C. peltata L. is the trumpet tree, so called from the use made of its hollow stems by the Uaupes Indians (Wallace, Amas. ch. XII). The hollows are often inhabited by fierce ants (Asteca sp.) which rush out if the tree be shaken, and attack the intruder. Schimper has made an investigation of this symbiosis (or

living together for mutual benefit) of plant and animal, showing that there is here a true case of myrmecophily as in Acacia sphaerocephala (q.v.). These ants protect the C. from the leaf-cutter ants. The internodes are hollow but do not communicate directly with the air. Near the top of each however is a thin place in the wall. A gravid ant burrows through this and brings up her brood inside the stem. The base of the leaf-stalk is swollen and bears food bodies (cf. Acacia) on the lower side, upon which the ants feed. New ones form as the old are eaten. Several other sp. show similar features. An interesting point, that goes to show the adaptive rature of these phenomena, is that in one sp. the stem is covered with wax which prevents the leaf-cutters from climbing up, and there are neither food-bodies nor the thin places in the internodes.

Cereus Mill. (BH. incl. Cephalocereus Pseiff., Echinocereus Engelm., Echinopsis Zucc., Pilocereus Lem.). Cactaceae (111. 1). 25 Am., W. Ind. Most are erect cylindrical forms, rarely branched, with root of less often mammillae (see fam.). C. giganteus Engelm. (Texas) is the largest of the cacti; it grows to 70 st. high and 2 st. thick with candelabra-like branching. C. grandistorus Mill. is the night-slowering cactus, whose sweetly-scented sts. open in the evening and wither before morning. Others, e.g. C. triangularis Mill., behave in the same way. These sp. are mostly trailing forms with adv. r. upon the stems. A number of cases of close resemblance may be sound between sp. of C. and sp. of Euphorbia. Fr. of most ed., often preserved.

Ceriferous, wax-producing. [Cf. Britton & Rose, Cactaceae. Cerinthe (Tourn.) L. Boraginaceae (1v. 4). 7 Eur., Medit.

Cerolepis Pierre (Camptostylus EP.). Flac. (1). None described.

Ceropegia L. Asclepiadaceae (II. 3). 120 Afr., As., Austr. Erect or twining herbs or undershubs, ± xero. Many have tuberous rootstocks, others are leafless and sometimes have fleshy Stapelia-like stems. The fls. form a trap like Aristolochia Clematitis. The C-tube widens at the base and at the top the teeth spread out, but in some they hold together at the tips, making a sort of umbrella. The tube is lined with downward pointing hairs, and small flies, attracted by the colour and smell, creep into the fl. and cannot escape till the hairs wither, when they emerge with pollinia on their proboscides.

Chenopodiaceae (A). 3 Medit., S. Afr. Chenopodiaceae (EP.; BH. incl. Basellaceae). Dicots. (Archichl. Centrospermae; Curvembryae BH.). 75 gen., 500 sp. with an interesting geographical distr., determined by the fact that they are nearly all halophytic. The 10 chief districts char. by their presence are (according to Bunge), (1) Austr., (2) the Pampas, (3) the Prairies, (4) and (5) the Medit. coasts, (6) the Karroo (S. Afr.), (7) the Red

Sea shores, (8) the S.W. Caspian coast, (9) Centr. As. (Caspian to Himalayas—deserts), (10) the salt steppes of E. As. The prevence of large quantities of salt in the soil necessitates the reduction of the transpiration, so that the pl. which grow in such situations exhibit xero. characters. They are mostly herbs (a few shrubs or small trees), with roots which penetrate deeply into the soil, and with 1. of various types, usu. not large, often fleshy, and often covered with hairs, which frequently give a curious and very char. mealy feeling

to the pl. In some halophytes of this fam. the l. are altogether suppressed, and the pl. has curious jointed succulent stems like a miniature cactus (e.g. Salicornia). Each 'limb' embraces the next succeeding one by a sort of cup at its apex. Even more than in their external form, the C. show xero. structure in their internal

anatomy.

Infl. often primarily racemose, but the partial infls. are always cymose, at first often dich., but with a tendency to the cincinnus form, by preference of the β -bracteole. The fls. are reg., small and inconspic., ξ or unisex. P simple, rarely absent, persistent after flowering, 5, 3, 2 (rarely r or 4) \pm united, imbr., sepaloid; A as many as or fewer than P segments, opp. to them, hypog. or on a disc; anthers bent inwards in bud; \underline{G} (semi-inf. in Beta), 1-loc. with 2 (rarely more) stigmas; ov. 1, basal, campylotropous. Fr. usu. a small round nut or achene; embryo usu. surrounding the endosp., either simply bent or spirally twisted. Few are useful; see Beta, Spinacia, Chenopodium, &c.

Classification and chief genera (after Volkens).

A. CYCLOLOBEAE. Embryo ring shaped, horseshoe-like, conduplicate or semicircular, wholly or partially enclosing endosp.; Polycnemum, Beta, Chenopodium, Spinacia, Atriplex, Camphorosma, Kochia, Corispermum, Salicornia.

B. SPIROLOBEAE. Embryo spirally twisted; endosp. wanting or divided into two masses by embryo; Sarcobatus, Suaeda,

Salsola, Haloxylon, Halimocnemis.

Chenopodium (Tourn.) L. Chenopodiaceae (A). 90 temp., 9 Brit. (goosefoot, lamb's-quarters, Good King Henry, &c.). Fr. in many dimorphic; some have horiz. seeds, some vertical (esp. on the term. twigs of the cymes). C. anthelminticum (ambrosioides) L. (worm-seed or Mexican tea) essential oil is used as a vermifuge in the U.S. C. Quinoa Willd. is a food plant in S. Am.; its seeds are boiled like rice. It and other spp. are used as spinach.

C. racemosa Nutt. (black snake-root, N. Am.) emetic.

Cinchona L. Rubiaceae (1. 5). 40 Andes. Trees. Fl. heterostyled in some. The source of Peruvian or Jesun's bark, from which are extracted the valuable drugs (alkaloids) quinine, cinchonidme, &c. The tree used to be cut down to obtain the bark and there was danger of extinction until cult. was started on a large scale. An expedition to the Andes in 1859 brought it to the east, where Ceylon took up its cult., and upon so large a scale as to reduce the price of quinine from 12s. to 1s. an ounce. Decrease in price, the lack of any improvement in the barks, and attacks of disease, made the cult. die out in Ceylon, and lava, where improvement was taken in hand, now almost monopolises it. India grows a good deal for supply to natives through the post offices. Several sp. are used, e.g. C. Calicaya Wedd. (yellow, and some crown, bark), C. Ledgeriana Moens (yellow bark, the richest in alkaloid), C. cordifolia Mutis (Cartagena bark), C. officinalis L. (condaminea H. & B.) (Loxa, crown or brown bark), C. succirubra Pav. (red bark). (Markham, Travels in Peru and India; Reimers, Les quinquinas de culture, 1900.)

Cinchonidin, Cinchona.

Cincinnobotrys Gilg. Melastomaceae (1). 2 trop. Afr.

Cincinnus, a monoch cyme in which the successive lat. branches fall alt. on either side of the relatively main axis; Bignoniaceae, Boraginaceae, Canna, Caryophyllaceae, Chenopodiaceae, Commelinaceae, Crassulaceae, Geramum, Helianthemum, Heliconia, Hydrophyllaceae, Hyoscyamus, Linaceae, Solanaceae, Strelitzia, Tradescantia, Urtica, Verbenaceae.

Gocos L. Palmae (IV. 2). 60 trop., esp. C. nucifera L. (coconut), cult. throughout trop. It grows esp. well near to the sea, and its fibrous and woody fr. is capable of floating long distances uninjured, hence it forms a char. feature of marine island veg., and indeed probably became widely distr. in early times. It is a tall palm with large pinnate I. and a dense monoec. infl. The stem rarely stands vertically, but makes a gradual curve; this would appear to be due to heliotropism. Fr. large, one-seeded. The outer layer of the pericarp is fibrous, the inner very hard (the shell of the coconuts sold in shops). At the base are 3 marks, corresponding to the 3 loc. of the ovary, two of which have become obliterated. Under one of these is the embryo. The thin testa is lined with white endosp., enclosing a large cavity, partly filled with a milky fluid. This palm furnishes many of the necessaries of life to the inhabitants of the tropics, and its products are largely exported from Ceylon, the Philippines, &c. The large I are woven into cadjans for thatching, mats, baskets, &c.: their stalks and midribs make fences, brooms, yokes, and many other articles of furniture. The bud or "cabbage" at the apex of the stem makes an excellent vegetable and is made into pickles and preserves. When flowering the infl.-axis is tapped for toddy, a drink like the Mexican pulque (cf. Agave), containing sugar. Evap. of toddy

furnishes a sugar known as jaggery; its fermentation gives an alcoholic drink, from which distillation produces the strong spirit known as arrack, while further fermentation gives vinegar. fr. while young contain a pint or more of a sweetish watery fluid, a refreshing drink; it decreases as the nut ripens. The kernels are eaten raw, or in curries, milk is expressed from them for flavouring, and oil is extracted by boiling or by pressure, in the latter case the kernels being first dried into what is known as copra. The refuse cake or poonac, left after the expression of the oil, is a valuable fattening food for cattle. The great use of the oil is for soap-making and margarine. In recent years a large industry has sprung up in desiccated coconut, largely used in confectionery, the kernel being sliced and dried in special desiccators. The outer wood of the stem (porcupine wood) is used for rafters, orn. articles, &c. The thick outer husk, rarely seen in Europe upon the nut, contains a large number of long stout fibres running lengthwise. The nut is placed in water till the soft tissues between these fibres decay, and the fibre (coir) is then beaten out; or sometimes the fibre is obtained by special machinery. [E. B. Copeland, The Coconut; Hunger, Cocos nucifera, Cocos or cocus wood, Brya Lbenus DC. [Nature, 124, 1929, p. 133.]

Codia Forst. Cunoniaceae. 9 New Caledonia. Codiaeum Rumph. ex A. Juss. Euphorb. (A. 11. 5). 6 Indomal., Polynes., Austr. Coffea L. Rubiaceae (II. 4). 45 palaeotrop., esp. Afr. C. arabica L. (Arabian coffee) largely cult. in S. Brazil, Java, Jamaica, and elsewhere, often under the shade of large trees. C. liberica Hierin (Liberian coffee) cult. usu. at lower elevations; its produce is not so good. Other sp. are also used. The fr. is a 2-seeded drupe, resembling a cherry. The pulp and the endocarp (which covers the two seeds like a layer of parchment) are mechanically removed. The seed, or coffee-bean, has a deep groove on the ventral side; by soaking it in water the endosperm is softened and the embryomay be dissected out. The stimulating property depends on the presence of the alkaloid caffeine. Coffee cultivation was from 1850 to 1880 the mainstay of Ceylon agriculture, but was killed out largely by the attacks of a fungus (Hemileia vaslatrix) and the green bug. By far the largest cult. is that of Brazil, which in 1912 exported 455 million worth of coffee. (Raoul, Culture du Caféier, Paris.) Coffee, Coffea arabica L., &c.; Kentucky-, Gymnocladus.

the & project beyond the mouth; cult. for food in Khasia Hills and Burma; used in medicine in China.

Cola Schott et Endl. Sterculiaceae. 50 Afr. C. vera K. Schumann and C. acuminata Schott et Endl. (possibly identical) are the source of the kola nuts which form a principal article of trade in W. Africa. The nuts contain much caffein, and when chewed confer considerable power of sustaining fatigue; they are consequently a staple in the diet of the negroes (cf. Erythroxylon). The tree is as yet rarely cult., but is very common in W. Afi. The nuts are skinned after keeping for a few days, and packed between 1. to keep them damp. Exalb.

Colax Lindl. (Lycaste Lindl. BII.). Orchidaceae (11. 14). 3 Brazil. Cult.

Colchicaceae (Warming) = Liliaceae (suborder I).

Colchicum L. Liliaceae (1). 45 Eur., W. As., N. Afr. C. autumnale L. (autumn crocus or meadow saffron), Brit. Below the soil is a large corm (fig. and description of corm &c. below). In autumn projects out of the soil. The P-tube is long, and the ovary remains below ground, protected from cold, &c. The protog. fl. is visited by

A, pl. in fl, in autumn, $\times \frac{1}{4}$ B, l, and opening fr. in following summer, $\times \frac{1}{4}$. C, underground portion of flg. pl. cut lengthwise; the thick outer line repres. the brown membrane enveloping the whole; to the right is the corm formed from the base of last year's shoot, a withered portion remaining at the apex; to the left is the flg axis, a lat shoot from the base of the corm; from the base of the axis spring r. and above are the l., sheathing and foliage; the fl. arises in the axil of one of the uppermost foliage l., which will appear above ground with the fr. next spring, when the lower portion of the axis will swell to form a new corm. Reduced. D, section of upper part of fl. $\times \frac{1}{2}$. E, ovary cut lengthwise. F, cross-section ovary. C, a single stigma. H, cross-section fr. I, ditto seed. BEGHI after Berg and Schmidt. E to G, and I enlarged, $H \times \frac{1}{2}$.

bees. In spring the l. appear and the capsule is brought above ground by the lengthening of its stalk. The seeds and corms are used in medicine, in gout.

Coldenia L. Boraginaceae (II). 15 trop., subtrop.

Coleanthers Stechard Franciscope (2) 2 W Au

Coleanthera Stschegl. Epacridaceae (3). 3 W. Austr.

Colladonia DC. = Prangos Lindl. p.p. (Umbellif.).

Collaca DC. = Galactia P. Bi. p.p. (Legum.).

Collar, junction of root and shoot.

Collards (Am.), a form of cabbage. Collateral branches, buds, cf. Buds.

Collecting (notes for field botanists, travellers and collectors).

OUTFIT. Any or all of the following may be needed, according to the places to be visited, and the kind of work to be done. All that is needed should be taken from the start, as it is usually difficult to get suitable things quickly elsewhere; extra supplies of paper, &c. may be sent to the "Poste restante" at places to be visited en route.

Portfolios for pressing plants as collected, lightly made of two strong cloth-covered pasteboards (17 in. × 11 in.) with encircling straps and handle, and to contain 30—50 sheets of paper. Specimens as collected are put at once into these, and time is thus saved in making large collections, e.g. on a journey in new country.

Collecting tins or vasculums of various sizes for bringing plants home

for further study. When slung on the back, the hinges should be on the lower side of the lid, and the bolt should slide downwards to fasten, otherwise it is liable to work loose. Small specimens are best carried in small round-cornered tobacco or tooth-powder tins, not among large ones in a general vasculum.

Presses for drying pl.; each of two outer frames of 1 inch iron rod 171 × 111 inches, filled in with stout wire netting soldered to the iron.

3 1 4

The papers lie between these frames and the whole is strapped with two stout straps to obtain the pressure.

Lattices, 17 × 11 inches, for admitting air between the masses of plants in the press, made of two sets of parallel thin laths fastened together.

Drying paper in sheets 17 × 11 inches in ample quantity; stout Manila is best, blotting paper is too fragile. Mounting paper in sheets 16½ × 10½ inches (standard size of Kew herbarium) or sheets of newspaper or other common paper for preservation of dry specimens removed from the press. Unfolded envelopes of thin paper cut into the shape shown, for seeds, flowers, &c.; place the specimen on 1 and fold over the wings 2, 3, 4, 5 in order. 2 must be the same size as 1.

Waxcloth for tying up bundles of dried and mounted specimens;

waterproof canvas for covers for presses, &c. in case of rain.

Corrosive sublimate (mercuric chloride) and alcohol for poisoning specimens; made up as required in the proportion of 1 part to 50. Large dish for poisoning. Naphthalin for keeping away insects.

Kerosine tins or other square tins with large lids for preserving specimens in alcohol (lids that push in airtight, as in many tobacco tins,

are the best); soldering apparatus for fastening up when full.

Bottles with stoppers for preserving delicate specimens; neckless glass tubes, with corks, of various sizes. Bottles are easily packed in

joints of bamboo, tubes in small tins.

Muslin for wrapping alcohol specimens. Each should be wrapped with its label (in Indian ink, or better on metal) in a piece of muslin and packed in the tin; specimens cannot then become mixed together, and can be closely packed.

Alcohol for preserving; ordinary methylated spirit is best for most

things, but some require 70 % alcohol, and some absolute alcohol.

Formalin, picric acid, chronic acid, glycerin, or other preservatives. Butterfly-net, killing-bottle, insect boxes, entomological pins, if ecological work is to be done.

Hunting-knife, cutlass, or kukri for lopping creepers, &c.; pruning shears for cutting branches; strong pocket knives; strong narrow bladed

trowels; geological hammer; strong rope for climbing, &c.

Travelling microscope and lenses; dissecting microscope; pocket lenses; microscope slides, cover-slips in alcohol or oil; scalpels; dissecting needles; scissors large and small and with fine points; razors for section-cutting; forceps; dishes; watch-glasses; camel-hair brushes.

Reagents and mountants for simple microscopic work, e.g. iodine, glycerine, haematoxylin, gold-size, canada balsam in xylol, alcohol, oil

of cloves.

Compass (prismatic by preference); spirit-level; aneroid barometer; thermometers (ordinary, maximum and minimum, wet and dry bulb); field glass (very useful for studying cliffs, ravines, trees, &c.); maps (geographical, geological, outlines for marking distribution, &c.).

Photographic camera and lenses; tripod; films or plates in soldered

tins; chemicals and dishes for developing, fixing, &c.

Drawing pencils (hard, medium, soit); drawing cards; sketch-block; colours; brushes; india-rubber; ink; compasses; ruler; scales in inches and centimetres; gum and brush; pins; pens; pencils; stylograph.

Spirit-lamp; tape-measure; string, twine and thread; thin wire; sheet-load or zinc for labels (if latter, also solution of platinic chloride for writing on it); glue-pot and glue for mounting.

Note-books with numbered detachable pages, so that the descr. of each specimen can be separated; consecutively numbered and perforated labels for specimens, the numbers to correspond to those in note-book. The labels may be joined to the pages or in sheets like postage stamps. More than one of each number will usu. be needed.

COLLECTING AND PRESERVING. The following hints will be found

useful.

Decide the general object of the work in advance, and collect principally for the furtherance of that object.

In collecting for subsequent distr., collect enough specimens to go

round, but do not seriously diminish a plant in its native locality.

Do not collect immediately on arrival; first become familiar with the plants and their local features and distribution. Better results are obtained by choosing certain localities as headquarters and working these thoroughly, than by rushing through a large district.

Do not collect herbarium material in wet weather.

Collect specimens which are as typical as possible, but also take some illustrating the range of variation, the difference of habit and size on different soils or situations, &c.

Collect entire pl. if possible, incl. r. In shrubs or trees, twigs with l. in all stages, portions of stem-bark and anything else necessary for a complete descr. Do not forget rad. l., buds, fl., ripe and unripe fr., seeds.

If a large collection is being made, it is quicker to use the portfolio than the vasculum, and to press each specimen as soon as obtained.

Large flowers or heads (e.g. thistles), fruits, roots, tubers, &c. may be sliced in half before pressing, or the surface only sliced off. Notes and sketches should be made of the original appearance.

L. of Conifers, Heaths, Succulents, &c. fall when dried, unless previously immersed a few seconds in boiling water. Do not

immerse fl

Thorny and prickly plants should first be placed between boards and pressed down with the feet; the prickles would otherwise tear the papers.

Delicate water plants should be arranged upon sheets of white paper.

under water, and always remain on these sheets while drying.

It saves time in drying delicate specimens to keep each always in a

folded sheet of very thin paper.

Place extra fl., small fragments, seeds, &c., in small envelopes, numbered to correspond with the specimens; do not have any small parts loose, or confusion may result.

Place all specimens in the press the day they are collected. Withered plants may be soaked in water; if the stem be cut 2-3 in. above the

former cut and under water it will often revive quickly.

Label every specimen with its consecutive number in such a way that the number cannot be lost. Punched labels are best, tied on with thread. See that all envelopes, &c. have the same number.

Spread out the specimens naturally. If many I. &c. overlap, place bits of drying paper between. If stems have to be cut, mark the corresponding ends by stars on the paper. Spread out some fl., leave others unspread, and divide some in the antero-post. plane. Divide some fr. lengthwise and crosswise.

Arrange the specimens on the sheets so that they form a steady pile without lumps in the middle. Place a lattice upon every five inches of When all are ready place in the press and draw the straps as tight as possible, or better, place about 10 lbs. weight upon it. Tighten the straps as the plants shrink.

Change drying papers at least once daily: dry used paper in the sun or by the fire; use warm driers where possible. See that petals, &c. do not stick to the paper: if necessary put slips of tissue paper

under.

In changing the papers, put the outer specimens inside, so that all shall dry evenly. Drying should be as rapid as possible to prevent loss of colour, blackening, &c.

Fully dried plants no longer feel cold on the cheek, and are stiff and

brittle.

Dried specimens should be poisoned by a brief immersion in 20/0 solution of mercuric chloride in alcohol. They should then be dried in the air, mounted (with glue) or laid between sheets of paper, and tied

up in wax-cloth with a little naphthalin to keep out insects.

Material for subsequent microscopic examination or for museums must usu, be preserved in alcohol. Cut into small portions, attach label (best of zinc written on with solution of platinic chloride, but paper and pencil or Indian ink will do temporarily); place in methylated spirit for a few days, wrapped in muslin, and finally preserve in large tin. A few inches of spirit at the bottom, enough to keep all specimens moist when the tin is soldered, will suffice for most material. Specimens for embryological, delicate histological, cytological, and other investigations, and delicate plants or organs, must be separately preserved from the first in absolute alcohol in bottles or tubes. Labels should be put inside these. Contents of bottles may be written on the ground surface of the stoppers, so as to be legible through the neck.

Museum material may also be preserved in formalin (1 part of ordinary solution to 10 or more of water). Some special preservatives, e.g. picric

and chromic acids, are used in special cases.

Specimens illustrative of economic uses of plants and their products should be collected in less known districts, e.g. samples of gums, resins, caoutchoucs, oils, fibres, timbers (portions of trunks, or slabs 8 x 4 x 4 inches), food-products, drugs, dyes, tans, &c. In all cases the exact origin should be verified, and herbarium specimens taken, bearing numbers to correspond with those placed on the products.

From less known countries, endeavour to bring back living seeds (ripe, well dried, dry in canvas bags, or packed in charcoal in tins if to be long kept), bulbs and tubers (gathered when dry and with withered leaves), succulent plants (gathered dry and loosely packed), living plants (planted in earth in Wardian cases or sometimes in bamboo pots. if possible some weeks before moving). Cuttings may sometimes be brought in oiled silk wrappers; pseudobulbs in boxes with air-holes; tree ferns with the fronds removed, and a ball of earth round the root.

RECORDING. The following hints are worth noting.

Make all notes immediately upon observation of the facts; never trust to memory, nor delay recording.

Make all notes about individual specimens upon detachable sheets,

numbered to correspond with the specimens; never describe two or more on the same sheet; never use the same number twice.

Make no record till satisfied of its truth and accuracy.

Accompany all notes with maps, drawings, sketches, or photographs

as far as possible.

Sketch and photograph all peculiarities of habit, characteristic forms of vegetation, and other features of interest. Mark all plants in such pictures with numbers corresponding to their numbers in your collection, and write a full description of each picture before leaving the spot. a photograph is taken, make a rough sketch (from the picture on the focussing screen or finder) of the scene and put numbers to the plants.

Label all specimens as collected with consecutive numbers, and subsequently with permanent labels (about 3 x 2 inches) giving name of herbarium, collection, tour or district in which they were collected,

date, locality, and collector, as well as the number.

As each specimen is gathered, record date, exact locality, elevation above sea, habit, colour of fl. and fr., scent, presence or absence of honey, floral mechanism, insect visits, and any other features and facts that cannot be ascertained from the specimens preserved.

Note the comparative frequency of each species, the kind of situation and soil it affects, and the species with which it is found in association.

Endeavour to note the chief general forms of vegetation and the local grouping of pl. in districts studied. Pay special attention to ecological and geographical questions.

Record native names (question several different persons before deciding), economic uses, and points of general or ethnological interest.

Further details of the subjects treated in this section may be found in Hints for Collectors (Kew Bulletin, 1914, p. 97), the Admiralty Manual of Scientific Enquiry, Dammer's Handbuch fur Pflanzensammier, Stuttgart, 1891, Asa Gray's Structural Bolany, &c. Collective (fr.), resulting from several fl., Ficus, Morus, Platanus.

Complicate, folded on itself.

Compositae (EP., BH.). Dicots. (Sympet. Campanulatae; Asterales BH.). The largest fam. of flg. pl., comprising about 900 genera, with over 13,000 sp.—more than 10°/0 of the total. They are distr. over the greater part of the earth. Although so large a fam. they are well marked in their characters and cannot be confounded with any other, though they have a superficial likeness to Dipsaceae and Calveeraceae.

Living in almost every conceivable situation, they present great variety in veg. habit, often within a single genus, e.g. Senecio (q.v.). Water and marsh plants and climbers are rare, and so also are epiphytes. This latter is interesting, for the distr. mech. of these pl. is admirably suited to an epiph. existence, and xero. is not uncommon. The enormous majority are herbaceous pl.; trees and shrubs are comparatively rare (about $\frac{1}{2} {}^0/_0$). It is worthy of note that the latter often form an important feature in the Composite flora of oceanic islands (see Wallace's Island Ly2).

L. usu. alt., frequently rad., opp. in Heliantheae, whorled in a few cases, e.g. Zinnia verticillata; stips. rarely present. R. usu. a tap-root, sometimes tuberous as in Dahlia, &c., often thickened like that of a carrot, e.g. Taraxacum, Cichorium, &c. For details of veg. organs refer to individual gen.; e.g. Aster, Barnadesia, Bellis, Bidens, Cichorium, Dahlia, Espeletia, Gnaphalium, Helianthus, Helichrysum, Lactuca, Mutisia, Petasites, Senecio, Silphium, Taraxacum, &c. All tribes exc. 12 and 13 contain oil-passages in the root, stem, &c. In 13 (Cichorieae), laticiferous vessels are present, commonly containing a milky white latex (e.g. lettuce, dandelion).

Infl. of racemose type, the fis. arranged in heads (capitula), or rarely in spikes. These heads are again arranged in many cases into larger infls.—racemes, corymbs, &c., or even into cpd. heads (Echinops, &c.). In this last case, however, the smaller heads (contain only one fl. each. Head surrounded by an invol. of bracts, usu. green, which performs for all the fis. of the head the functions that in most plants are performed by the calices of the individual fis., viz. protection of the bud and of the young fr. Fls. arranged upon a common receptacle—the enlarged end of the axis—of various shapes, most frequently flat, slightly convex or even spindle-shaped. The shape and surface-condition of the receptacle are chars. of

importance in classification of the fam. It may be smooth or hairy, &c.; there may (Helianthus, &c.) or may not (Calendula, &c.) be, upon it, scaly br. belonging to the individual firs. In Cynareae these br. are divided so as to form numerous bristles.

In the simplest case the fls. of a single head are all alike and y, but there are many deviations from this type. The fls. may be all actinomorphic (tubular) or all + (ligulate); see below. Very commonly however, as in daisy or sunflower, there is a distinction into a disc of actinomorphic fls., and a marginal ray of . fls. Or, as in Centaurea sp., the outer florets may be actinomorphic but different in size from the central. The number of ray-florets varies in different sp., but according to definite rules.

The distribution of sexes among the fls. of a head varies much. The most common case is gynomonoecism, the ray-florets ?, the disc ?. The very large ray-florets of Centaurea sp. and others are completely sterile (cf. Hydrangea, Viburnum, &c.). Cf. also Tussi-

lago, Petasites, &c.

The flower is fully epig., usu. 5-merous. K absent in Ambrosia and its allies, Siegesbeckia, &c.; in some cases it appears only as a slightly 5-lobed rim upon the top of the inf. ovary (cf. Rubiaceae and Umbelliferae); usu. it takes the form of hairs or bristles-the pappus-and enlarges after fert. into a parachute (Dandelion) or into hooked bristles (Bidens) to aid in distr. (see below). C (5), valvate in bud; actinom. (tubular) or +. Of the latter form there are two varieties, labiate (lipped) and ligulate (strap-shaped). The latter term, strictly speaking, should be applied to those corollas which are strapshaped in form with 5 teeth at the end repres. the petals, but is usu, also given to those lipped forms where the lower lip is strap-shaped and ends in 3 teeth. Sta. 5, epipet. with short

Floral Diagram of Composite fl with pap-pus (after Eichler). The small outer lines represent the pappus-bristles

filaments, alt. with the petals. Anthers intr., cohering by their edges (syngenesious), forming a tube around the style (cf. Lobelia). G (2), with a simple style that forks at the end into two stigmas, an ant. and a post. (see diagram). The construction of the style and stigma is of importance in the classification. There is often a brush of hairs on the style below the stigmas. Only the inner (upper) surfaces of the stigmas are as a rule receptive to pollen. Ovary 1-loc. with r erect, basal, anatr. ov., which gives an exalb. seed with straight embryo, enclosed in the dry indeh. pericarp. This fr. is usu. termed an achene, but of course is, if one adhere strictly to definitions, a pseudo-nut, as its pericarp is partly axial, and there is > one cpl. It is often crowned with a pappus (see below).

- Natural History of the Flower. Being massed together in heads, the individual fls. may be, and usu. are, comparatively very small, and the advantage is gained that a single insect visitor may fert. many fis. in a short time without having to fly from one to the other, while there is no loss of conspicuousness, and a considerable saving of corolla-material, &c. Throughout the fam., the same type of mech, of the individual fl. is found, the differences being slight and unimportant. It is simple, but effective. Honey is secreted by a ring-shaped nectary round the base of the style, and protected from rain and from short-lipped insects by the tube of the C. The depth of the tube varies within fairly wide limits, but is never so small as to permit the shortest-lipped insects to obtain the honey. As a fam, the C. all belong to Muller's fl. class B', but there is considerable variety in the depth of tube, &c., and therefore also in the composition of the group of visiting insects to each. Thus the long-tubed purple-flowered Centaureas, &c. are mainly visited by bees and Lepidoptera, while the short-tubed yellow Leontodons or white Achilleas are visited mainly by flies.

At the time when the fl. opens, the style, with its stigmas tightly closed against one another, is comparatively short, reaching up to, or projecting a small distance into, the anther tube. The pollen is shed into this, and as the style grows it presses the pollen little by little out at the upper end of the tube where it will come into contact with visiting insects. At last the style itself emerges and the stigmas separate. The fl. is now ?. Finally, in a great many cases, the stigmas curl so far back that they touch the pollen upon their own style, so that every fl. is certain to set seed, even though it be by selffert. In a few cases, e.g. Senecio vulguris, insect visitors are very rare, and the fl. depends entirely on self-fert. The mech. is about the simplest and most perfect that exists for attaining the desired ends. A striking contrast is seen in the orchids; they have bizarre fls. with most elaborate mechs., and an enormous number of seeds in every caps. An interesting modification of the mech. is found in Cynareae (see Centaurea) where the sta. are irritable. See also Artemisia (wind-fert.).

The invol. bracts, or ray florets, or both, often close up over the central fls. in cold or wet weather, thus protecting the fls.

Natural History of the Fruit. The ripening fr.-head is generally protected from injury by the invol. bracts, which bend inwards over it, performing the function of a K. The calices of the individual fis. are thus rendered useless in this respect and are, in most C., used for purposes of distr. of the fr. In most cases, the K, after the fert. of the fl., grows into the familiar pappus, as seen in dandelions or thistles, usu. composed of fine hairs, often branched, but in some cases, e.g. Achyrachaena, leafy and membranous. The hairs are hygroscopic and spread out in dry air; this often helps to lever the fr. off the receptacle. In Adenostemma the pappus is sticky. In Bidens and others the pappus is formed of stout barbed bristles; the fr. adheres to animals. In Arctium the invol. br. become hooked at the tips and cling to animals. In Xanthium the recept. is provided with hooks. In Siegesbeckia the bracts are sticky. A few genera, e.g. Helianthus, Bellis, &c., have no special arrangements at all, and the frs. remain upon the common receptacle till jerked off by wind or otherwise.

General Considerations. The C. are generally regarded as occupying the highest position in the Veg. Kingdom. Their success

may be put down perhaps to the concurrence of several useful peculiarities, viz.

(1) the massing of the fis. in heads, surrounded by invol. bracts:

from this there results

- (a) greater conspicuousness, especially when ray-florets are developed;
 (b) a saving of material in the corollas, &c.;
 (c) the fact that one insect visitor may fertilise many fls. in a short time without having to fly from one to another:
- (2) the very simple and effective floral mechanism, which ensures (d) protection of honey and pollen; (e) exclusion of the very short-lipped (allotropous) insects, but not too great specialisation for a very narrow circle of visitors; (f) prevention of self- and chance of cross-fertilisation till the last possible moment; (g) certainty of self-fertilisation if the cross fails;
- (3) the use of the calices of individual fls. for purposes of seed-distribution, and the very perfect character of the mechanism.

These considerations should be compared with the features of rival

fams., e.g. Cruciserae, Gramineae, Rubiaceae, Leguminosae.

Economic uses. The C. furnish but few useful plants (other than border or greenhouse pl.). See Lactuca, Cichorium, Cynara, Heli-

anthus, Carthamus, Chrysanthemum, Tanacetum, &c.

Classification and chief genera (after Hoffmann). The classification of the C. and the determination of their genera is a matter of no small difficulty; we shall give only the primary groupings and their chief genera. [There are several exceptions to the characters given below.]

[Abbreviations: cap. = capitulum; tub. = tubular; lig. = ligulate; homog. = fls. in head all similar as to sex; heterog. = fls. of different

sex in one head, e.g. ray ? and disc ?.)

1. Vernonieae (cap. homog.; fls. tub., never yellow; anthers arrow-shaped at base, pointed or rarely tailed, with filaments inserted high above the base; stigmas semicylindrical, long, pointed, hairy outside); stigmatic papillae all over inner surface: Vernonia, Elephantopus.

 Euratorieae (cap. homog.; fls. tub., never pure yellow; anthers blunt at base, with filaments inserted at base; stigmas long, but blunt or flattened at tip, with very short hairs; stigmatic papillae in marginal rows): Age-

ratum, Eupatorium, Mikania, Adenostemma.

3. Astereae (cap. heterog. or homog.; all or only central fistub.; anthers as in 2; stigmas flattened with marginal rows of papillae, and terminal hairy unreceptive portions): Solidago, Bellis, Aster, Erigeron, Baccharis, Callistephus, Olearia.

 Inuleae (as 3; corolla in tub. fls. with 4-5-toothed limb; anthers tailed at base; styles various): Blumea, Filago,

Antennaria, Gnaphalium, Helichrysum, Inula.

- 5. Heliantheae (style with crown of long hairs above the division; anthers usu. rounded at base with basally inserted filaments; corolla of disc fls. actinom.; pappus not hairy; invol. bracts not membranous at margins; recept. with scaly br.): Espeletia, Silphium, Xanthium, Zinnia, Siegesbeckia, Helianthus, Dahlia, Bidens, Cosmos,
- 6. Helenieae (as 5, but recept. without scaly br.): Helenium, Tagetes.
- 7. Anthemideae (as 6, but invol. br. with membranous tip and edges; pappus o or abortive): Achillea, Anthemis, Chrysanthemum, Matricaria, Tanacetum, Artemisia.

Senecioneae (as 5 and 6, but pappus hairy): Tussilago, Petasites, Senecio, Doronicum.

Calenduleae (cap. with ? ray fls, and usu. & disc fls., with undivided style; anthers pointed at base; recept. not scaly; no pappus): Calendula.

Arctotideae (style, below or at point of division, thickened or with circle of hairs; cap. with lig. ray fls.; anthers acute at base or with longer or shorter point and with filaments inserted above the base): Arctotis.

Cynareae (style as in 10; cap. homog. or with neuter, II. rarely ?, not ligulate, ray fls.; anthers usu. tailed; recept. usu. bristly; Echinops, Carlina, Arctium, Carduus, Cnicus, Cynara, Centaurea, Carthamus, Saussurea.

12. Mutisieae (cap homog. or heterog.; ray fls. when present usu. 2-lipped; disc fls. actinom. with deeply-divided limb, or 2-lipped): Barnadesia, Mutisia, Stifftia, Gerbera.

B. I.IGULIFLORAE. All fls. ligulate. Latex.

Cichorieae: Cichorium, Rhagadiolus, Picris, Crepis, Hieracium, Leontodon, Taraxacum, Lactuca, Tragopogon, Scorzonera, Sonchus.

Compound (1.), where the stalk bears several leaflets; (head), Angianthus, Echinops; (fr.), aggregate, Anona, Ranunculus, Rubus. Compressed, flattened.

Concolor (Lat.), of uniform colour.

Concrescence, union of originally distinct organs by growth of the tissue beneath them. Organs in the earliest stages of development are usu. separate, and most often remain so, but frequently there is a subsequent

growth of tissue under them, carrying them out upon a basal portion which most often (e.g. in sympet. fls.) has a similar structure to the organs themselves, so that they look as if joined together by their bases. The diagram shows this process on the right, but not on the left. It is

leaf By University leaf

common in fls., less so in other organs. It is not necessary for the concrescent organs to be similar; e.g. sta. are often united to pets., l. to stems (cf. Solanaceae, &c.). The phenomenon goes under names—adnation, connation, adhesion, cohesion, &c. Cf. figures of Concrete, growing together. [Zostera, Solanaceae, &c.

Congou, Thea.

Coniferae. The most important class of Gymnosperms, and like the others better represented in former ages than now. They form a fams. with 41 gen. and 380 sp. Like their past history, their present geographical distr. is of interest. Most are erect evergr. trees, and grow in dense forests, forming char. features of the veg. in many regions (esp. temp. and subtrop. and mountains). Beginning in the north we find Juniperus nana beyond the limit of trees. This limit is largely marked by the C. and the birch. Within it, in the N. temp. zone, are broad areas covered with C. (Larix, Abies, Pinus, &c.). Going S., their importance decreases, and at about 40° N. they become practically confined to the mountains. Here we find in Japan and China a region of development char. by Cephalotaxus, Pseudolarix, Cryptomeria, Cunninghamia, Sciadopitys, Chamaecyparis, Keteleeria, Glyptostrobus, Taiwania, &c.,

mostly endemic gen. In Pacific N. Am. is another region, with Pseudotsuga Douglassi, Sequoia, Taxodium, Chamaecyparis, Lawsoniana, Thija gigantea, and Libocedrus decurrens, together with endemic Abies, Tsuga, Pinus, &c. The Himal forms another great centre, with many peculiar sp., e.g. Cedrus Deodara, Pinus excelsa, and others, Picea sp., Tsuga sp, &c. The C. of the * are separated from those of the * by a broad band of trop. forests, &c., partially broken by groups of C. on the Mts. of the Indomal region and Am. In Austr. we find Araucaria, Agathis, Podocarpus, Callitris, Microcachrys, Athrotaxis, Actinostrobus, &c. In Tasm., N.Z. and Chili appear Phyllocladus, Fitzroya, &c. S. Am. has Araucaria sp., Podocarpus sp., and others. Few gen and sp. of C. appear in both N. and S. hemispheres; each sp. is limited to a well-defined area.

Trees or shrubs, usu. monopodial, often of considerable or even (Sequoia) gigantic size. Typically, as may be seen in a fir or larch plantation, a certain amount of growth is made each year and a number of branches are also formed much at the same level, so that in trees of moderate size the number of 'whorls' of branches is an index of the age. Later on the lower branches usu. die off and the branching near the apex becomes less reg. The main stem is radially symmetrical, but the branches, which often grow almost horiz., have a tendency to dorsiventrality, expressed in a two-ranked airangement of the l., twisting of the l. on their stalks, and so on. Many C. show a difference in their shoots; some (long shoots, or shoots of unlimited growth) grow continuously onwards, except for the interruption in winter; others (short shoots, shoots of limited growth, or spurs) grow only to a definite size, usu. very small, and bear a few l. Intermediate conditions occur in Larix, Cedrus, Taxodium, &c. both kinds occur the foliage l. are often borne on the short shoots only (see Pinus &c. for details). The green I. are usu. entire and are either needle-like, flat and linear, or closely appressed scales (Cupressus, &c.). Mention may be made of the curious 'doubleneedles' of Sciadopitys and the flat green short shoots of Phyllocladus (q.v.).

Anatomically, the C. resemble Dicots. in all important points. A very general feature (exc. Taxus) is the presence of resin passages in all parts of the pl. The l. exhibit a somewhat peculiar internal structure, suited to xero pl., under which class most C. come, living

in cold soil, as most do, and often with evergr. l.

In the fl. we are met with great difficulties. There are two theories about its morphology, those of Eichler (Bluthendiag. or Nat. Pfl.) and of Celakovsky (see Warming's System. Bot. or Bot. Jahreto. 1890, p. 324, also Noll in Bot. Centr. 60, p. 131]. We cannot discuss these (see Worsdell, in Ann. of Bot. 14, 1900, p. 39), but shall merely state both. As the order is usu. classified according to the Eichlerian view, we have adopted this in the classification and the details of the gen.

The fls. of C. appear as a rule in the form of cones, and are always unisex., mon- or dioecious. They are never term. on the main stem as in Cycads, but are usu. borne lat. near to its apex. Sometimes (as in Pinus 3) the cones are massed together in spikes or heads,

Both theories agree about the & fl., which is usu. a cone or catkin The sta. may be flat, but is commonly of sta. on a central axis. ± peltate, and bears a number of pollen-sacs (not > 9 as a rule) on its lower surface (see Pinus, Taxus, &c.). In the ?, the cone (to avoid for the present the word flower) consists typically of an axis bearing leaf-like organs. The most familiar case is Pinus (q.v.), where each l. borne on the axis is a small scale, bearing on its upper surface a very large scale (these latter show on the outside of the

cone) on the upper side of which, again, are the two ovules. We may diagrammatically represent it thus, using 'cover-scale' to express the lower, 'ovuliferous scale' (epimatium) the upper, of the two scales. In Cryptomeria, &c. we find a large scale borne directly on the axis, with a little flap on its upper side near the outer end, and the ovules at the base. The flap is, by both theorists, supposed to represent the ovuliferous scale, and so we have what is illustrated by the second diagram. Then in Cupresscae, &c. we find only one scale, and here the two theorists differ. In the other fam., Taxaceae, still further difficulties meet us. In Microcachrys the ovule is borne upon a 1. of the cone, but in Phyllocladus it is axillary and in Taxus term. (see these gen.). In most C. there is only one integument, but in Taxaceae a second commonly appears, forming an aril, ± fleshy, round the seed as

it ripens.

cover-scale ovules ovulif. scale cover-scale ovules

ovulif sc. }
cover-scale } ovules ovulif. sc.) cover-scale

ovules

Now as to the explanation of the facts. Eichler regards the whole cone as one ? fi. with a number of cpls. (the 'cover-scales'). The cpl. may bear the ovule directly, as in the latter cases above mentioned, or may develope upon its upper surface a placenta (ovulif, scale) which bears the ovules. Cryptomeria thus represents a stage in this evolution, and the whole may be compared with the division of a l. into a sterile and fertile part, as in Ophioglossum. The rival theory of Celakovsky regards each ovule or pair of oyules with its appurtenances as a ? fl. (one cpl. to each ovule or pair) so that the cone is a spike of fls. A series may be thus drawn: Podocarpus (one cpl., one ovule with two integuments, the whole in the axil of a cover-scale, which is therefore to be regarded as a bract), Taxus (fl. reduced to ovule, aril = outer integument); then in the Pinaceae we have spikes of fls. (cones), the cover-scale being the bract, the ovuliferous scale the combined outer integuments of the ovules of two cpls. (or three, the keel on the middle of the scale in Pinus, &c. repres. the third): a fusion of the bract with the fl. in its axil is supposed to have gone on, and we get next the Cryptomeria type, and finally that of Cupresseae.

Ovules orthotr., exc. Podocarpus. For development of the ovule. fert., &c., see text-books. The cone often becomes hard and woody as the seeds ripen; in other cases it becomes fleshy. The seeds contain

an embryo with 2-15 cotyledons, and rich endosp.

Natural History. The C. are entirely wind-fert.; the pollen is light and powdery, sometimes provided with air-bladders (e.g. Pinus), and is produced in enormous quantities. About the time it is shed the scales of the 2 cones open to receive it and the grains adhere to the sticky fluid at the apex of the ovule. Fert. often does not take place for a long time afterwards (see Pinus).

The seeds in many genera with woody cones (e.g. Pinus) are winged for wind-carriage; in other genera they are animal distributed,

e.g. Juniperus (cone fleshy), Taxus (fleshy aril), &c.

Further details of morphology, life history, &c. under Gymnospermae, Pinus and other gen. See also Retinospora for the peculiar

case of pl. retaining the 'seedling' form throughout life.

Economically the C. are most important, furnishing the greater proportion of our timber, as well as resins, tars, turpentines, &c. See gen., esp. Abies, Pinus, Larix, Tsuga, Libocedrus, Juniperus, Taxus, &c.

Classification and Key to Genera (after Eichler and Engler):

- Fam. 1. TAXACEAE. Mostly dioecious; cone-formation imperfect; cpls. usu. few or even 1 terminal, with 1-2 ov. each; seeds projecting beyond cpls., or even naked, with fleshy aril or drupaceous testa; chiefly *.
- Anther with 2 pollen-sacs; cpls. 1—∞, with 1 ov., often very small; ovuliferous scale in all but Pherosphaera, often united to integument. I. PODOCARPOIDEAE.
 - a. Ovuliferous scale o; ov. at base of cpl., erect; l. scaly.

1. Pherosphaereae.

1. Pherosphaera. b. Ovuliferous scale present; l. usu. linear.

Podocarpeae.

Ov. scale and integument separate. I. Cpls. many; ov. scale membranous, little enlarged.

1. Cpls. whorled, thick, obtuse; seeds free; l. scaly.

Microcachrys. 2. Cpls. spiral, imbr.; seeds in groove at base, small; fr. cpls. united; l. linear.

Saxegothaea.

II. Cpls. 1-few; ov. scale developed; young ov. ± pend, ultimately mostly upright, rarely stationary, enclosed in ov. scale. 4. Dacrydium.

B. Ov. scale completely curved into itself, united with integument of pend. ov., falling with seed; cpls.

usu. small, much shorter than ov. 5. Podocarpus.

B. Anther with 2 loc.; cpls. with 1 ov.; seeds surrounded by cupule; twigs phylloclades with tooth-like 1.-rudiments.

II. PHYLLOCLADOIDEAE. 6. Phyllocladus. Only genus

- C. Anther with 3-8 loc.; cpls. with 2 ov., or fl. reduced to 1 ov. term. on axis covered with scale 1.; ov. scale o; seeds with cupule, exc. in 7. III. TAXOIDEAE.
 - a. ? fl. of several decussate cpls.; cpl. with 2 ov.

 Cephalotaxeae. Cephalotaxus.

- b. 8 fl. reduced to 1 ov. term. on axis covered with scale 1. 2. Taxeae. a. 9 fl. in pairs in axil of 1., each with 4 decussate scales; Torreya. anther 4-loc. 8. B. 9 fl. usu. single, only one of pair developed, the common axis with scale 1.; anther 6-8-loc. Taxus. Younger ? fl. unknown; position doubtful, ? Podocarpoideae; sta. 2-loc.; ? fl. term. or 2-3 at tip of twig; cpls. 1-2. 10. Acmopyle. Fam. 2. PINACEAE. Mostly monoecious; cones perfect; seeds concealed between scales; testa woody or leathery; no aril. L. spirally arranged; sta. with several long pollen-sacs; cpls. simple, with I reversed ov. in centre. I. Araucarieae. Seeds free from cpl. Agathis. united to cpl. Araucaria. I 2. L. spirally arranged; cover and ov. scales, the latter usu. large, with 2 ov. II. Abieteae. Long shoots only present. a. Needles 4-angled; cone pend.; scales persistent. 13. Picea. β. Needles flat. L. with I central resin canal; cone pend.; scales 14. Tsuga. persistent. II. L. with 2 lat. resin canals; cone pend. or erect; sta. fl. sol. or umbellate. 15. Pseudotsuga. III. Cone upright with persistent scales. 16. Keteleeria. IV. Cone upright with deciduous scales. 17. Abies. b. Long and short shoots both present. a. Long shoots with scale 1. only; the green (needle) 1. on the short shoots. 18. Pinus. Needle l. on both shoots. I. Needles evergr.; fr. 2-3 yrs. in ripening. 19. Cedrus. Deciduous; fr. 1 yr. in ripening. Cone scales persistent. 20. Larix. Cone scales deciduous. 21. Pseudolarix. C. L. spirally arranged; scales rudimentary or weakly developed
 - reversed on edges of cpls. III. Taxodieae.

 a. Long shoots with scale 1.; short shoots = double needles.

 b. Long shoots only.

 22. Sciadopitys.

into cover and ov. scales; ovules 2-8, axillary and erect, or

- a. Seed reversed.
 - I. Cpl. minute. China, Cochinchina.

Ovules 3. 23. Cunninghamia. Ovules 2. 24. Taiwania.

Cpl. with ridge-like inner scale. Tasmania, Austr.

Cpl. shield-shaped, no distinct ov. scale. N. Am.

Conjugate, coupled.

Connaraceae (EP., BH.). Dicots. (Archich. Rosales, EP., BH.).

16 gen., 160 sp., trop.; closely allied to Leguminosae, chiefly distinguished by the absence of stips. and the (usual) presence of > 2

1215. Moetly twiping chambe with all and repisles of

2 green l. annually. Fls. homogamous, self-fert. Cult. orn. fl. Convallariaceae (Warming) = Liliaceae (§§ VI-XI).

Convolute (aestivation), cf. Aestivation.

Convolvulaceae (EP.; BH. incl. Nolan.). Dicots. (Sympet. Tubiflorae; Polemoniales BH.; pp. xlv, liii). 50/1000, trop. and temp., herbs, shrubs or rarely trees, many climbing, some thorny xero., Cuscuta a climbing parasite. Some with tuberous roots or stems, others with rhiz.; latex often present. L. alt., usu. stalked, rarely stip., often with accessory axillary buds. Infl. dich, with tendency to cincinnus or bostryx; br. and bracteoles present, sometimes close to K.

Fl. &, reg. hypog. usu. 5-merous. K, rarely (K), imbr., odd sep. post., seps. sometimes unequal; (C) of various shapes, usu. induplicatevalv., sometimes conv.; A 5, alt. with C, epipet., on base of C, anthers usu. intr.; G on honey-secreting disc (2), rarely (3-5) or only joined by style, 2-loc. with axile plac.; ov. 2, rarely 1 or 4, per loc., erect, anatr. or \(\frac{1}{2}\)-anatr., micropyle facing outwards and downwards; ov. with one integument. Berry, nut, caps.; endosp. Fl. usu. large and showy. Many have extrafloral nectaries on petiole. Few of economic value except for handsome fls. (cf. Ipomoea).

Classification and chief genera: closely related to Solan., Borag., and other Tubiflorae. Cf. Nat. Pfl.

CONVOLVULOIDEAE (independent green pl.).

1. Dichondreae (G usu. divided, forming 2 or 4 1-seeded mericarps): Dichondra (2 meri.), Falkia (4), only gen.

2. Dicronostyleae (G simple; style long ± bifid, or 2), 5merous, stigma capitate or slightly lobed): Breweria, [brandtia (only gen.). Dicranostyles, Evolvulus.

3. Hildebrandtiene (do. stigma irreg. lobed): Hilde-

4. Convolvuleae (style united to stigma): Argyreia, Porana, Aniseia, Mina, Quamoclit, Exogonium, Ipomoea, Pharbitis, Jacquemontia, Convolvulus, Calystegia.

Erycibeae (style extremely short): Erycibe (only gen.). CUSCUTOIDEAE (leasless parasites; no cots.): Cuscuta (only gen.). Dichondraceae and Cuscutaceae are some-

times made separate fams.

Convolvulus (Tourn.) L. Convolv. (1. 4). 180 temp., a few trop. C. arvensis L. (Brit.; bindweed) has sweetly scented fis., more visited by insects than the large but scentless fls. of Calystegia sepium. Smaller fls. with short sta. appear on some stocks; these appear to be due to the action of a fungus (cf. Lychnis). Veg. repr. by adv. stem buds produced on the root. From incisions in the rhiz. of C. scammonia L. flows a resinous purgative juice (scammony). Some yield rosewood oil. Cult. orn. fl. Convolvulus, Calystegia, Convolvulus.

Corunastylis Fitzgerald. Orchidaceae (II. 2). I Austr.

Coryanthes Hook. Orchidaceae (II. 13). Ó trop. S. Am., epiphytic. Fl. pend.; seps. bent back and fairly large, pets. small. Labellum complex, forming a bucket-like organ with dome above; the mouth faces upwards, and the edges are incurved; there is also an overflow pipe projecting towards the seps. and closely covered in by the bent end of the column, with the stigma and anther. From the base of the column project two horns which secrete a thin watery fluid that drips into the bucket, keeping it full to the level of the overflow pipe. The dome (above) is composed of succulent tissue attractive to bees; these fight for places on it to drill the tissue; every now and then one gets pushed off and falls into the bucket. It can neither fly nor climb out, and has to squeeze through the overflow pipe. In so doing it first passes the stigma, fertilising it if it bears any pollen, and then, passing the anther, is loaded with new pollinia. [Darwin's Orchids, p. 173, and cf. Stanhopea.]

Corybas Salisb. = Corysanthes R. Br. (Orchid.).
Corycium Swartz. Orchidaceae (II. 1). 10 S. Afr.

Corydalis Vent. Papaveraceae (III). 140 Medit., Eur., As. C. claviculata DC. Brit., a (leaf) tendril-climbing annual. Most are perennial herbs with underground tubers. In C. cava Schweigg. et Kort., and others, the main axis forms a tuber, which dies away below, each annual shoot arising from the axil of a scale-l. of older date. In C. solida Sw., and others, the tuber is a swollen root-structure belonging to the current annual shoot. Fls. transv. + (see fam. for diagram); twisting through 90° brings it vertical; only one petal is spurred and contains the honey secreted by a staminal outgrowth. Its mech. resembles that of Leguminosae. The inner pets., united at the tip, enclose stigma and anthers; the upper pet. covers the fl. Bees alighting push down the inner pet. and cause the essential organs to emerge. In some, e.g. C. ochroleuca Koch and C. lutea DC., the emergence is explosive (cf. Genista). The fls. of C. cava are self-sterile.

Corylopsis Sieb. et Zucc. Hamamelidaccae. 25 China, Japan. Fls. &,

in spikes with coloured bracts at base.

Corylus (Tourn.) L. Betulaceae (1). 8 N. temp. C. avellana L., hazel-nut (Brit.). Shrubby (largely owing to extensive formation of suckers), with monoecious catkinate fls. (the ? catkin sessile and elliptical in outline, rather resembling a bud). Both are laid down in autumn; the & catkins are visible all winter, but the ? are not obvious until the red stigmas come out early in the year. Anemoph.;

the fact of flg. before the appearance of the l. renders their chance of fert. greater. On the inner side of the br. in the catkin are found a scales and, adnate to these, 4—8 sta., each

branched nearly to the base. Here only the central fl. of the possible 3 (cf. diagram of fam.) is present, with its bracteoles a, \(\beta \). In the \(\beta \) catkin, on the other hand, we have the two lat. and not the central fl. as shown in the second diagram (*=missing fl.). At the time of fert, the ovary is minute, but the long red stigmas are easily identified. After fert. the ovary (2-loc. at first) gives a one-seeded nut, enclosed in a cup of green leafy nature, really the combined bract and bracteoles α , α' , β' , very much developed.

stem ∂A. bract

stem

a' a ? fl. ₽ fl. ß β ß bract

The fl. is chalazogamic (cf. Chalazogamae). The nuts of this and other sp. are valuable as dessert fr., &c. (hazel-nut, cob-nut, filbert), and have been cultivated from very early times (cf. Goeschke, Die Haselnuss, Berlin, 1887). Wood elastic, but cannot be obtained in large boards. Oil from the seeds.

Planch., trop and S. Afr. Cult. orn. fl.

Crocus (Tourn.) L. Iridaceae (1). 60 Medit., Eur., 2 nat. in Brit. Below ground is a corm (cf. Colchicum), covered with a few scaly 1., in whose axils may arise one or more buds, giving rise to new corms on the top of the old. The l. are dorsiv., and curiously grooved on the back. The fl. is often single and term.; in some sp. there is a small cyme. The fl. closes at night and in dull weather. The tube of the P is so long that the ovary remains below the soil and is protected from the weather (cf. Colchicum). The fl. is protandr. and visited by bees and Lepidoptera. Honey is secreted by the ovary, and the anthers face outwards so as to touch any insect alighting on the petals and seeking honey. The stigmas are branched. Birds often bite off the fis. in gardens (? for honey); they seem to prefer the yellow fls., leaving the blue and white alone.

The dried stigmas of C. sativus L. form saffron, once largely used as an orange yellow dye, but now chiefly employed in flavouring and colouring dishes, liqueurs, &c. [See Kronfeld's Geschichte des Safrans. &c., Wien 1892. Cult. orn. fl. (Maw, The genus C.).]

Crucianella L. Rubiaceae (II. II). 4 Eur., Medit. Cult. orn. fl.

Cruciate, cross-shaped.

Cruciferae (EP., BH.). Dicots. (Archichl. Rhoeadales; Parietales BH.). 220 gen., 1900 sp., cosmop., but chiefly N. temp. and esp. Medit.; a very natural fam., well marked off from others, though approaching Papaveraceae and Capparidaceae. Herbs, a few undershrubs; some ann., many perenn., forming each year a new shoot term. in the infl. L. usu. alt., exstip., with unicellular simple or branched hairs. For other peculiarities of veg. organs see gen., e.g. Brassica, Anastatica, Subulaiia, Vella, &c. Infl. usu. a raceme or corymb, and nearly always without bracts or bracteoles.

Fl. usu. &, reg., hypog., with typical formula K 2+2, C4, A6,

G(2). The K has two whorls, the C only one, alt. with the K as a whole. The petals usu. spread out in the form of a cross and are often clawed; the sta. in two whorls, an outer of 2 short, an inner of 4 long, sta. (tetradynamous); anthers intr. The two cpls. are placed transv., and have parietal plac., but the ov. is 2-loc. on account of the presence of an antero-post. partition, the replum or so-called spurious septum, an outgrowth of the placentae. Stigmas 2, on short style, above the placentae (cf. Papaveraceae). Ovules anatro or campylotr.

Floral Diagram (after Eichler).

The explanation of the morphology of this fl. has given rise to much dispute. It is usu. regarded as a typically 2-merous fl. (cf. Papaveraceae), and the 4 petals and 4 inner sta. are supposed to be due to branching. Others regard it as 4-merous (c.g. Klein in Bot. Centr. 58, p. 197). Full discussion in Eichler's

Bluthendiagr. or in Asa Gray's Struct. Bot. p. 206.

On the bases of the sta. are the nectaries, the honey being secreted into the often gibbous bases of the inner sepals. The sepals often stand almost straight up, and the petals are then provided with claws and spread out horiz. beyond the sepals. The honey is thus concealed to some extent and protected from rain. The majority of the order exhibit this construction more or less, thus coming into the biological fl.-class AB. In many gen. the fls. are arranged in corymbs, thus getting the advantage of many fls. massed together on one level (cf. Umbelliferae and Compositae). Insects visiting the fls. touch the anthers with one side of their bodies and the stigma with the other, and may in this way effect cross-fert., as they go sometimes to one, sometimes to the other, side of the fl. Dichogamy is frequent, but not well marked, and in almost all self-fert. ultimately occurs. [Müller, Fert. of Fls.]

Fr. a caps, of pod-like form; if at least three times as long as broad it is called a *siliqua*, if shorter a *silicula*. It is divided into two by the replum and is usu, thin and membranous. The valves break away from below upwards, leaving the replum with the seeds pressed against it and adhering. The fr. may be flattened in two

ways, either || or 1 the replum; this char. is of systematic importance. It may also be jointed between the seeds as in a lomentum (Leguminosae). Achene-like one-seeded fr. occur in a few gen. Others have

subterranean fr. (Cardamine sp., &c.).

For plants of economic value see esp. Brassica (which gives a number of valuable vegetables), Sinapis, Nasturtium, Lepidium, &c. All C. are harmless, and most are rich in sulphur compounds (to which the smell of boiling cabbages is due), and are thus useful in

scurvy, &c.

Classification and chief genera (after Prantl):

The grouping of the smaller divisions of the fam. and the defining of the genera is a most difficult task. Many classifications have been devised. Prantl (in Nat. Pfl.) bases his largely upon the hairs borne on the leaves. Others rely on characters of fruit and embryo, &c. In any case the identification of a cruciferous genus is a difficult matter. A. Hairs simple or none: no glandular hairs.

 Thelypodicae (stigma equally developed all round; style undivided or prolonged above middle of cpls., or turned back):

Pringlea, Thelypodium, Heliophila.

2. Sinapeae (stigma better developed over placentae): Subularia, Lepidium, Iberis, Cochlearia, Alliaria, Sisymbrium, Cakile, Isatis, Vella, Sinapis, Brassica, Raphanus, Crambe, Nasturtium, Cardamine, Lunaria.

. Hairs branched (a few exceptions): sometimes also glandular

hairs,

3. Schizopetaleae (stigma equal all round): Schizopetalum,

Physaria.

 Hesperideae (stigma better developed over placentae): Capsella, Draba, Arabis, Erysimum, Cheiranthus, Alyssum, Anastatica, Malcomia, Hesperis, Matthiola, Conringia.

Oucurbitaceae (EP., BH.). Dicots. (Sympet. Cucurbitales; Polypet. Passiflorales BH.). 90 gen., 750 sp., wanting in the colder regions, most abundant in the trop., chiefly climbing ann. herbs with very rapid growth and abundance of sap in their stems and other tissues. L. alt. roundish, entire or lobed. They climb by tendrils, about whose morphological nature there has been much discussion; they have been considered by various authors as "roots, stems, leaves.

stipules, shoots, flower-stalks or organs sui generis." According to Muller (Nat. Pfl.) the tendrils of Cucurbita Pepo, with their frequent abnormalities, give a proof of their true nature. Every variety is found, from simple threads to long leafy tendrils, in which the l. show all transitions to tendrils. Muller, therefore, considers the twining portion of the tendril to be a met. I., the lower stiff portion a stem. The tendrils of C. are very sensitive and show very well all the

phenomena of tendril-climbing.

Fls. diclinous, rarely \(\frac{1}{2} \), in infls. of various types (see Nat. Pfl., or Eichler, Bluthendiagr.). K and C typically (5) each, reg.; A typically 5, but great var. is introduced by cohesions, &c.; it is almost always +. In Fevillea we find 5 sta. with biloc. anthers, the simplest type; it is noteworthy that the usual 4-loc, anther never occurs in C., and no trace of the missing loc. is to be found in either lobe of the anther of Fevillea. In the rest of the fam. the A is more complex. In Thladiantha two pairs of sta. stand apart from the fifth sta. In Sicydium these pairs show union of their members at the base, and in others the union is more complete, until, as in Bryonia, &c., the A apparently has only 3 sta., of which 2 have 4-loc, anthers due to unions. The more the sta. depart from the simple type the more curved do the loculi of the anthers become, till in Cucurbita, &c. the pollen-sacs are twisted in a most extraordinary manner (cf. Columellia). In Cyclanthera the sta. are all united into a column with two ring-shaped pollen chambers running round the top (cf. the flowers of Cyclanthus). G 1-10-loc., with 1-∞ anatr. ov. in each loc.; the most common type is, however, a 3-loc. ovary with axile plac. projecting deep into the cavity. Stigmas as many as cpls., usually forked. Fr. usu. fleshy, of the type of the melon or cucumber—berry-like, sometimes called a pepo. Seeds exalb. In Zanonia, Echallium, Cyclanthera, &c. (q.v.), the mode of seed-dispersal is interesting. Several have ed. fr., e.g. Cucurbita, Cucumis, Sechium, Lagenaria, &c.

The relationships of this fam. have been much disputed. It has been placed near Passifloraceae, Loasaceae and Begoniaceae, but

most probably it comes near to the Campanulaceae.

Classification and chief genera (after Pax):

A. Pollen-sacs not fused into a ring. a. Sta. free or only united at base.

1. Fevilleeae (sta. 5, rarely 4): Fevillea, Zanonia, Thladiantha.

2. Melothricae (sta. 3, rarely 2 or 4; pollen-sacs straight or slightly curved): Melothria, Telfairia.

Cucurbiteae (do., but pollen-sacs S or U shaped): Acanthosicyos, Momordica, Luffa, Bryonia, Ecballium, Cucumis, Lagenaria, Trichosanthes, Cucurbita.

Sta. united into a column.

Sicyoideae: Echinocystis, Sechium, Sicyos.

B. Pollen-sacs fused into a ring.

5. Cyclanthereae: Cyclanthera (only genus).

Cuscus (khas-khas), Vetiveria zizanioides Stapf.

Cuscuta (Tourn.) L. Convolvulaceae (II). 100 trop. and temp.; 3 Brit. (dodder, scald, &c.). Many have extended their boundaries through being carried about with their host plants. Leasless and rootless total parasites. The stem twines and is sensitive to contact like a tendril so that it clasps the support tightly; it rarely makes more than three turns about the same branch of the host. At the points in close contact suckers are developed which penetrate the tissues of the host, growing into organic union with them and drawing off all the food

materials required by the parasite, which has no green tissue of its own. The seeds of C. germinate later than those of the host plant; a very short anchorage root is formed and the stem nutates in search of a host; as soon as it has clasped one the root dies away. Much damage is often done by these plants: most of the Brit. sp. confine themselves to particular host pl., but others attack a variety of pl. For details see Kerner's Nat. Hist. of Plants, vol. 1., and papers by Peirce in Ann. of Bot. 1893-4. Cushion plants, with cushion-like growth reducing evap. Cusickia M. E. Jones. Umbelliserae (III. 6). IN. Am. Cusparia Humb. Cycadaceae (chiefly after Eichler). Gymnospermae. 9 genera with about 75 sp., the survivors of a group of plants which in past ages figured more largely in the flora of the earth, reaching their maximum about the end of the Triassic and beginning of the Jurassic period. They represent the lowest type of living seed plants and in appearance and habit are like tree-ferns. The stem is usu. short and stout, only growing to any noteworthy height in Cycas itself, and is often tuberously swollen; it shows a secondary growth in thickness. It has a long primary tap root. In some sp. a sort of felt-work of roots is formed at the base of the stem, and a number of short lat. branches of these stand erect and may emerge from the soil (see Nat. Pfl.). The stem has usu. a crown of leaves, and its lower portion is covered with scales. There are, in all except a few sp. of Macrozamia, two sorts of 1., foliage- and scale-1., borne spirally upon the stem, and alt. with one another, as a rule several circles of scales before each circle of foliage l., which they protect in the bud. The scales are really 1. bases whose blades abort. The foliage 1. are very char. They possess usu. a thickened, woody, ± sheathing base, which often persists after the fall of the rest of the 1. There is a stout rachis or petiole, frequently thorny at the base, the thorns being 'metamorphosed' leaflets. Upon its upper side are two grooves, from which spring the leaflets, which may or may not be opp. to one another; there is usu. no term. leaflet. The leaflets may be entire or toothed and are usu. very rigid and leathery. Three types of nervalure occur:

midrib, no lateral nerves: Cycas.

midrib and lateral nerves: Stangeria. (2)

numerous parallel or wavy, simple or forked nerves running (3)

longitudinally: the other genera.

The fls. are dioec. and usu. take the form of cones; these arc term., and so the stem becomes a sympodium, except in Cycas and some spp. of Encephalartos, &c., where the stem 'grows through' the fl. or fls. The size of the cones varies considerably. Each consists essentially of a central axis bearing a number of fertile l. or sporophylls; occasionally the lowest 1. are sterile as in Coniferae. In the cone, the l. (scales) are generally of a sort of nail shape (cf. Equisetum), and bear sori upon the lower side, each of 2-6 sporangia (pollen-sacs), arranged with the lines of dehiscence radiating from the common centre. In the 2 cone the scale (cpl.) is of somewhat similar shape but bears as a rule only two sporangia (ovules), whose apices are directed towards the axis of the cone. Cycas (q, v)has no proper cone, but the stem bears a whorl of cpls. in place of ordinary 1. The ovule is large, orthotr. with one integument. The pollen is carried by the wind to the micropyle, where it germinates.

The ov. grows into a large seed; testa two-layered, the inner woody, the outer fleshy. Endopleura on the seed. Nucellus reduced to a thin cap on the top of the seed, the bulk of which is endosp. with straight embryo in centre. 2 cots., usu. united at the tips.

The C. are exclusively trop. and subtrop. Of the genera, 4, 7, 8, g are from Am., 3 and 6 Austr., 2 and 5 Afr., whilst Cycas is found in E. Ind., Austr., and the islands of Ind. and Pacif. Oceans.

Classification and Genera (after Eichler):

Cycadeae (cpls. with 8-4, rarely 2 ovules; stem growing through the ? fl.; leaflet with midrib only): 1. Cycas. Zamieae (ovules 2; stem not growing through):

Pinna pinnately nerved 2. Stangeria. longitudinally nerved

Leaf bipinnate ,, once pinnate

,, in & flat, in ? peltate. 9. Microcycas. 16 trop. E. Ind., Austr., Polynes. For gen. ,, Cycas L. Cycadaceae. 16 trop. E. Ind., Austr., Polynes. For genchar., &c., see fam. The ? pl. does not bear a cone, but a whorl of cpls. of a woolly brown appearance; in notches upon the margins of these are the naked ovules, usu. 4-8 in number. Stems reaching 50 ft. in some sp., usu. unbranched. The pith of C. circinalis I.. trop. As., sometimes called sago-palm) and C. revoluta Thunb. (Japan) yields a sago. Literature in Coulter and Chamberlain, Morphology of Gymnosperms (q.v.).

Cyclachaena Fresen. (Iva EP.). Compositae (5). 2 N. Am. Cycladenia Benth. Apocynaceae (II. 1). 2 California.

Cyclamen (Tourn.) L. Primulaceae (2). 18 Eur. (mostly alpine), C. europaeum L. Brit. (sow-bread). There is a stout corm (cf. Colchicum) due to thickening of the hypocotyl. The P-lobes are bent back and the fl. is pend., with loose-pollen mechanism (cf. Acanthus, Erica). After fert, the stalk usu, coils up spirally, drawing the ripening fr. down to the soil (cf. Vallisneria); in C. persicum Sibth. et Sm. it bends over and forces the fr. into the ground (cf. Arachis). Cult. orn. fl.

Cyclanthaceae (EP., BH.). Monocots. (Synanthae; Nudiflorae BH.). 6 gen., 45 sp. trop. Am.; they help to char. the flora of this region. Climbers, epiph., rhiz.-herbs, or small shrubs, of palm-like habit, with curious spadix infls. on which the and ? fls. alt. in various ways (see Carludovica and Cyclanthus). Fr. multiple, fleshy. Endosp. The fam, is nearly related to Palmae, Pandanaceae and Araceae.

Chief genera: Carludovica, Cyclanthus.

Sta. com-Cyclanthera Schrad. Cucurbitaceae (5). 30 trop. Am. bined into a column as in section 4, but here the anther-loculi fused into 2 ring-shaped loculi running completely round the top of the column. C. explodens Naud. has explosive fr. (cf. Ecballium); the pericarp is extremely turgid on its inner surface, and the fr. dehisces into valves, each of which rolls back on itself with a jerk.

Cyclantheropsis Harms. (Gerrardanthus p.p.). Cucurb. (4).

Cyclanthaceae. 4 trop. Am., W.I. The rhiz. Cyclanthus Poit. bears large 1., forked into two at the top. Infl. term. on a long stalk, as a large cylindrical spadix with big bracts at base, resembling a number of discs piled upon one another, with their edges sharpened to a thin rim. In some two || spirals compose the spadix, each with a sharpened edge. In the former case every other disc bears o fls., in the latter one of the spirals, the other being ?. The & fls. occupy a groove at the edge of the rim; each has 6 sta. and no P. The 2 fls. are embedded in the disc; ovaries united into a long continuous chamber running all round the disc and containing numerous placentae. Ps united all round the disc; on their inner sides they bear Fr. multiple, consisting of a number of seeds embedded in a general fleshy mass formed of ovaries and spadix. Cf. Carludovica. Cyclea Arn. Cynanchum L. (incl. Vincetoxicum Rupp.). Asclepiadaceae (II. I). 120 trop. and temp., many twiners, and zero. with fleshy stems and reduced 1.; fls. fert. by carrion-flies which get the pollinia attached to their proboscides.

Cynapium Nutt. = Ligusticum L. (Umbell.).

Cynara Vaill. ex L. Compositae (11). 11 Medit. C. Scolymus L. is the true artichoke (cf. Helianthus); young fl.-heads enclosed in the invol. bracts, a valuable pot-herb. The blanched summer growth (chards) is also ed. C. Cardunculus L. is the cardoon, whose l. are blanched and eaten like celery; it has spread over great areas on the Pampas, where it was introduced.

Cynaropsis O. Ktze. (Cynara p.p.). Compositae (inc. sed.). 1

Canaries.

Cyno- (Gr. pref.), dog-.

Cynocrambaceae (Thelygonaceae) (EP. Urticaceae p.p. BH.). Dicots. (Archichl. Centrospermae). One genus, Cynocrambe (q.v.), which is so anomalous that it has been placed near to Urticaceae (united BH.), Phytolaccaceae (united by Warming), Chenopodiaceae, Begoniaceae, Santalaceae, Monimiaceae, &c. (see Nat. Pfl.).

Cynocrambe Tourn. ex Adans. (Thelygonum L.). Cynocrambaceae (only gen.). 2 Canaries, Medit., C. As. Herbs with fleshy stip. 1. the basal opp. Fls. unisex., the d opp. the l., with P 2-5, A 10-30; 2 in 3-fld. axillary cymes, with P 3-4; G 1, style basal, ov. 1.

Drupe. Endosp.

Cynoctonum E. Mey. = Vincetoxicum Moench. (BH.) = Cynanchum L. Cynodon Rich. Gramineae (11). 3 Austr., 1 C. Dactylon Pers. (dog's-tooth or Bermuda grass), cosmop. (incl. Brit.). It grows with creeping stems on sandy soil and is used for binding dunes; useful pasture. Spikes digitate, spikelets r-fld.

Cynoglossum (Tourn.) L. Boraginaceae (IV. I). 60 temp. and subtrop. 2 Brit., incl. C. officinale (hound's tongue). Formerly offic. Fr. hooked.

Cynomarathrum Nutt. (Peucedanum p.p.). Umbell. (111. 6). N. Am.

Cynometra L. Leguminosae (II. 2). 40 trop. C. cauliflora I. is a good example of stem-fruiting or cauliflory.

Cynomoriaceae (EP.; Balanophoraceae p.p. BH). Dicots. (Archichl.

Myrtiflorae). Only genus Cynomorium, q.v.

Cynomorium Mich. ex. L. Cynomoriaceae. 1 Medit., C. coccineum L. Rhiz. brownish, total parasitic herbs with polygamous fis. \$ fl. with epig. sta. Ovule 1, pend.

Cynorchis Thou. (Cynosorchis). Orchid. (II. 1). 15 trop. Afr., Madag. Cynosciadium DC. Umbelliferae (III. 5). 3 N. Am.

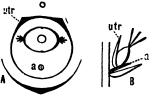

Cynosurus L. Gramineae (10). 5 Old World temp., 2 Brit. (dog's-tail grass), one, C. cristatus L., a valuable pasture and fodder.

Cypella. Herb. Iridaceae (II. 1). 5 temp. S. Am. One sp. unfolds its fls. in great numbers at definite times.

Cypellium Desv. Inc. sed. 1 Guiana.

Oyperaceae (EP., BH.). Monocots. (Glumiflorae; Glumaceae BH.). 85 gen., 2600 sp., cosmop., chiefly marsh-pl. Grass-like pl. (sedges), mostly perenn. with creeping sympodial rhiz. The new shoot of each year is adnate, for an internode or more, to the parent shoot, so that the branching seems at first sight extra-axillary. The aerial shoot is usu. grass-like, but the stem solid and angular with 3 ranks of l. The l. is sheathing at the base, but the sheath is entire, not split as in a grass. The unit of infl. is again a spikelet; the total infl. may be a spike or panicle as in grasses. In many sedges the spikelet is cymose—a sympodium

—and should perhaps be termed a pseudo-spikelet. The fl. is borne in the axil of a glume and may be \(\frac{1}{2} \) or unisexual; it is usu. naked but may have a P of 6 (or \(\infty\)) small scales or hairs; A 3, \(\frac{G}{2} \) (3) or (2), I-loc., with long feathery (anemoph.) stigmas; ovule I, basal, anatr. In Carex, &c., the \(\frac{2}{2} \) fl. is borne in the axil of a second glume (the utricle) which closely enwraps it (in the figure it is shown diagrammati-

Diagrams of Carex (after Eichler) A, diagram of a 2-carpelled 9 ftr, B, side view of 9 ftr a. = axis of spikelet; utr. = utricle.

cally). The fis. are wind-pollinated. Fr. an achene, the testa not adhering to the pericarp. The sedges are of little economic value; see Cyperus.

Classification and chief genera (after Engler):

I. SCIRPOIDEAE (fls. § in many-fld. spikelets, or single § with or without trichomes): Cyperus, Eriophorum, Scirpus, Eleocharis, Fimbristylis.

II. RHYNCHOSPOROIDEAE (fls. § or 8 9 with or without trichomes in few-fld. spike-like cymes aggregated into spikes or heads): Schoenus, Cladium, Rhynchospora, Mapania, Scleria.

III. CARICOIDEAE (fls. & ?, naked, usu. in many-fld. spikes; ? enclosed by utricle): Carex, Uncinia.

Cyperorchis Blume. Orchidaceae (II. 17). 3 Himal. Cult. orn. fls.

Cyperus L. (incl. Mariscus Gaertn.). Cyperaceae (1). 400 trop. and warm temp. (2 Brit.). Herbs with sympodial rhiz. and leafless or leafy shoots above ground. Infl. umbel- or head-like. C. Papyrus L. (paper-reed) is a river-side plant with shoots 3—12 feet high. From the stems was made the ancient writing paper, papyrus. stem was split into thin strips, which were pressed together while The rhiz. is ed., and also the root-tubers of several sp.; still wet. the stems (whole or split) of many are used for basket making. &c. cyphel, Arenaria Cherleria Hook.

Cyphia Berg. Campanulaceae (II). 25 Afr. [Cyphiaceae, Warming.] Cyphocarpa Lopriore. Amarantaceae (2). 10 trop. and S. Afr.

Cyphostigma Benth. Zingiberaceae (I). 15 Ceylon, Malaya. Cypress Cupressus; -pine (Austr.), Callitris; Sitka-, Chamaecyparis;

swamp-, Taxodium.

Cypripedium L. Orchidaceae (1. 2). 30 N. temp. and subtrop. (C. Calceolus L. in Brit.). Lady's-slipper orchids. Terrestrial acranthous plants. Lat. sepals completely united. Labellum slipper-like with inturned edge; at its base is the column, partly enclosed in it. The large std. (see fam.) is visible outside the labellum; under it are the two anthers, and lower down the flat stigma. Pollen glutinous not united into pollinia. Insects (mostly bees) visiting the fl. get inside the labellum and cannot get out by the way they entered, so have to pass out by the openings at the base, in doing which they brush against the stigma and then the anthers.

Cypselea Turp. Aizoaceae (II). I W. Indies.
Cypselocarpus F. Muell. Chenopodiaceae (inc. sed.). I W. Austr.

Cypselodontia DC. Compositae (4). 1 S. Afr.

Cyrilla Garden. Cyrillaceae. 3 warm Am., marsh plants with

evergr. 1., and fls. in racemes below them.

Cyrillaceae (EP., BH.). Dicots. (Archichl. Sapindales; Olacales BH.). 3 gen., 6 sp. Am. Evergr. shrubs with alt., exstip. l. and racemes of \$\forall \text{, reg. firs. K 5, imbr., persistent; C 5 or (5), imbr.; A 5+5 or 5, with intr. anthers; G (5-2) multi-loc. with 1 (rarely 2-4) pend. anatr. ov. in each loc.; raphe dorsal, micropyle facing upwards and inwards. Embryo straight, in endosp. Genera: Cliftonia, Costaea, Cyrilla.

  Brit.
         The l. in this sp. are reduced to scales and assim. is chiefly
   performed by the stems. The fl. has an explosive mech., in general
   like Genista (q.v.), but different in detail. The style is very long
  and there are two lengths of sta., so that pollen is shed near the tip
   of the keel (where also is the stigma) and also about half way along
   its upper side. When an insect alights on the fl. (there is no honey),
   the keel begins to split from the base towards the tip, and presently
   the pollen of the short sta, is shot out upon the lower surface of the
   visitor; immediately afterwards, the split having feached the tip, the
   other pollen and the style spring violently out and strike the insect
   on the back. As the stigma touches first there is thus a chance of a
   cross, if the insect bear any pollen. Afterwards the style bends right
   round and the stigma occupies a position just above the short sta.,
```

so that another chance of cross-fert. is afforded if other insects visit the fl. (in most exploding fls. there is only the one chance). Other sp. have simple mechanisms like Trifolium. The fr. explodes by a

twisting of the valves.

C. Adami Poit is a curious graft-hybrid between C. purpureus Scop, and Laburnum vulgare. The latter was used as the stock; the shoots above the graft exhibit hybrid characters (see Darwin, Variation under Domest. ch. XI). Recently this matter of chimeras (halfand half shoots, &c.) and graft-hybrids has been much investigated. See review in Bot. Gazette, 51, 1911, p. 147.

Deschampsia Beauv. Gramineae (9). 20 temp. and fiigid. D. caespitosa Beauv. (Aira) and D. flexuosa Trin. in Brit. (hair grass); of

tufted growth; rough fodder grasses.

Description of plants. Root, stem, leaf, flower, and fruit, &c. are described for floras, &c. in concise technical terms (original descriptions of new species must be in Latin), which are mostly given here under fl., l., &c. The descriptions of families in this book may serve as examples for large groups, and as examples of a species described in full detail we may refer to any numbers of the Journ. Linn. Soc. or to Lindley's Descriptive Botany, from which we quote as instances:

lilac (1.): 1. opp., exstip., roundish-cordate, very acute, thin, smooth, rather longer than the linear channelled petiole.

buttercup (fl.): fl. term., sol., on long angular and furrowed peduncles, reg., &, hypog. Sepals 5, polysep., oval, coloured at edge, reflexed, with shaggy hairs. Petals 5, polypet., roundish, concave, with wedge-shaped basal nectaries, bright yellow. Stamens ∞ , polyandrous, spiral; filament yellow, slender; anther linear, adnate, extrorse. Carpels ∞ , apocarpous, superior, collected into a nearly spherical head, greenish; stigmas sessile, recurved; ovules solitary, ascending, anatropous.

But if all the species in a genus are known, it is obvious that for purposes of description to enable identification, such a description is much too long, and the skill of the describer will be shown in describing those characters only in full (or as fully as necessary) which are essential to the discrimination of the species among its congeners.

Dicentra Bernh. Papaveraceae (111). 15 As., N. Am. D. Cucullaria Bernh. (Dutchman's breeches) and others cult. orn. fl. The rhiz. of many sp. (§ Cucullaria) resembles a succession of bulbs, on account of the fleshiness of the scale 1. and of the sheathing bases of the fol. 1. The materials formed in the 1. during the growing season are stored up in the fleshy base, which survives the winter, while the rest of the 1. dies. Fls. in racemes, pend. Each outer petal has a large pouch at its base. The inner petals are spoon-shaped and cohere at the tip, forming a hood which covers the anthers and stigma. The pends position and complex structure of the fl. render it suited to bees, which hang on to it and probe for honey first one side, then the other, in the pouches of the petals. In so doing they push aside the hood and touch the stigma, on which there is usu. pollen from its own sta.

Diomedia Cass. = Borrichia Adans. (Comp).

Dionaea Ellis. Droseraceae. 1 Carolina, D. muscipula Ellis (Venus' fly-trap), in damp mossy places on the 'pine-barrens.' Short rhiz. bearing a rosette of l., which lie close to the soil. Each has a lower and an upper blade; the former may be regarded as a winged petiole. the latter has a quadrangular shape and the margins project as long teeth close together. The two halves of this part of the l. are bent upwards so as to present a flat V-form in section. The edge of each half is green, the inner part of the surface is covered with reddish dots, which under the microscope are seen to be digestive glands; unless stimulated, no secretion is carried on. On each half of the 1. are three long hairs—the trigger-hairs—jointed at the base so that they fold downwards when the l. closes. The slightest touch to one of these, or a more vigorous stimulus to the surface of the l., causes an immediate closing. The teeth cross one another, and if an insect cause the movement, it is thus captured. The closing of the l. still continues till the two halves are tightly squeezed together. Then the digestive glands commence to secrete a ferment which acts upon the proteids of the prey and renders them soluble, when they are absorbed by the l. (cf. Drosera). When the process is complete the l. opens again. [Macfarlane in Contrib. from Bot. Lab. Pennsylv. Univ. 1. 1892.]

Dioncophyllum Baill. Flacourtiaceae (5). 1 Congo.

Dionychia Naud. Melastomaceae (1). 2 Madagascar.

Dionysia Fenzl. Primulaceae (1). 20 alpine Persia, Afghanistan.

Dioon Lindl. Cycadaceae. 3 Mexico. The seeds are ground into meal, which contains much starch.

Dioscorea Plum. ex I. Dioscoreaceae. 600 trop. and subtrop. D. pyrenaica Bub. et Bordère (Pyrenees) is the only Eur. sp. They have twining annual stems arising from tubers which in different sp. are of different morphological nature. In D. Batatas Done., &c. the tuber arises by a lateral hypertrophy of the hypocotyl, and is variously regarded as a rhiz. or a root; in D. sinuata Vel., &c. it arises by lateral hypertrophy of the internodes above the cotyledon; in D. pentaphylla L., &c. it arises from the internode just above the cotyledon together with the hypocotyl, whilst in D. villosa, L., D. quinqueloba Thunb., &c., there is a fleshy rhiz. The tubers are known as yams; they contain much starch and are largely cult. for food in trop., esp. Am. The best are perhaps D. alata L. (white yam), D. cayennensis Link (negro yam), D. trifida L. f. (cush-cush; yampi). They are propagated by 'eyes' like potatoes. Small axillary tubers often form on the main stem and may also be used.

Dioscoreaceae (EP, BH.). Monocots. (Liliiflorae; Epigynae BH.). 9 gen., 220 sp., trop. and warm temp., climbing herbs or shrubs with tubers or rhizomes at the base (morphology varied; see gen.). Lalt., net-veined, often arrow-shaped; infl. racemose; fls. reg., usu. dioec., inconspic. P (6), tubular at base; A 6, or 3 and 3 stds.; \overline{G} (3) usu. 3-loc. with axile, rarely 1-loc. with parietal, plac.; ov. usu. 2 in each loc., anatr. one above the other. Capsule or berry; embryo in horny endosp. The tubers of Dioscorea are valuable as food stuffs; those of Testudinaria are also used. Chief genera: Dioscorea, Testudinaria, Tamus.

Dioscoreophyllum Engl. Menispermaceae. 5 trop. Afr. Dioscoreophyllum Engl. (Menisp.). Diosma L. Rutaceae (1). 11 S. Afr. Heath-like xerophytes. Diosphaera Buser. Campanulaceae (1. 1). 3 E. Medit.

Disarticulate, to separate at a joint.

Diso, a flattening of the receptacle above the K, Anacardiaceae, Celastraceae, Rutaceae; epigynous in Umbelliferae, &c.; -flower, Compositae; -oid, like a disc.

Disanthus Maxim. Hamamel. 1 Japan.

Discaria Hook. Rhamn. 15 S. Andes, Brazil, N.Z., Austr. Cult. orn. Dischidia R. Br. (incl. Conchophyllum Blume). Asclep. (II. 3). 70 Indomal., Polynes., Austr. Epiphytic, climbing by advent. roots, and

with fleshy l. covered by wax. The curious pitcher-plant, D. Rafflesiana Wall., besides the ordinary I., has pitcher-l. Each is a pitcher with incurved margin, about 10 cm. deep. Into it grows an adv. r. developed from the stem or petiole just beside it. The pitcher may hang with its mouth upwards or may stand horizontally or upside down. It usu contains a lot of debris, largely carried into it by nesting ants. Most contain ± rain water, so that perhaps they act as humus collectors and water reservoirs. The inner surface is waxy, so that the water cannot be absorbed by the pitcher itself, but must be taken up by the roots.

Developmental study shows the pitcher to be a l. with its lower side invaginated. The existing sp. illustrate all stages. Many, e.g. D. bengalensis Colebr., have bi-convex l.; others have the under surface concave, e.g. D. (C.) Collyris Wall., and the roots are developed under and sheltered by the concave l. A further invagination would lead to D. Rafflesiana. (Treub in Ann. Buitenz. 111. 1883, Haberlandt's Tropenreise, p. 168, and two papers in Ann. of Bot.

Dispersal of seeds may be occasional, as by floating trees, ice, &c., tornados, mud on birds' feet, the voiding of the crops of carnivorous birds, &c. (see Origin of Species, chap. XII), or regular, by ways which may be classed in four heads. By wind are carried directly the spores of ferns, &c., seeds of Pyrola, Orchidaceae, some Caryophyllaceae, &c., by censer-mechanisms (see Aconitum), Campanula,

Carvophyllaceae, Delphinium, Iridaceae, Liliaceae, Papaver: winged seeds in Bignoniaceae Bromeliaceae, Casuarina, Millingtonia, Pinus, Zanonia; winged fruits in Abronia, Aceraceae, Bignoniaceae, Carpinus, Dipterocarpaceae, Fraxinus, Liriodendron, Malpighiaceae, Ptelea, Pterocarpus, Rumex, Serjania, Terminalia, Tripteris, Ulmus, Ventilago; hairs, forming a parachute mechanism, in seeds of Apocynaceae, Asclepiadaceae, Epilobium, Gossypium, Salix, &c., in fruits of Anemone, Clematis, Compositae, Eriophorum, Typha, Valerianaceae, &c.

By animals are carried, as inside passengers, the seeds in edible fruits (q.v.), and as outside passengers the hooked fr. of Asperula, Bidens, Blumenbachia, Cenchrus, Circaea, Daucus, Galium, Geum, Harpagophytum, Martynia, Medicago, Tragoceros, Triumfetta, Xanthium, &c., the glandular fr. or seed of Allionia, Boerhaavia, Pisonia, Plumbago, Siegesbeckia, &c. By water Cerbera, Cocos, Crinum. Nuphar, Nymphaea, Potamogeton, &c. By explosive mechanisms are scattered the seeds of Alstroemeria, Balsaminaceae, Biophytum, Buxus, Cardamine, Cyclanthera, Dorstenia, Ecballium. Elaterium, Eschscholtzia, Geranium, Hura, Impatiens, Ricinus, Ulex, Viola, &c. As a general rule, the dispersal of seed by any of these mechanisms is only to a very small distance, but they may at any time be of great importance by enabling transport over long distances.

Dropwort, Filipendula vulgaris Moench.; water-, Oenanthe.

Drosera L. Droseraceae. 90 trop. and temp. 3 in Brit. (sundew). D. rotundifolia L. abundant in bogs. Herbs usu, with creeping rhiz. and rosettes of l., insectivorous. The blade of the l. is circular in some sp., elongated in others, and is set with curious tentacles; these are emergences containing vascular bundles and ending in swollen reddish heads which secrete a sticky glistening fluid. Flies and other insects mistaking it for honey are held by it. The tentacles are exceedingly sensitive to continued pressure even by the lightest bodies; the result is to cause an inward and downward movement of the head of the tentacle, finally placing the fly upon the blade At the same time the stimulus passes to the surrounding tentacles causing them also to bend downwards to the same point. The victim is thus smothered and now the glandular heads of the tentacles secrete a ferment which acts upon the proteids and brings them into solution, when they are taken up by the 1. Afterwards the tentacles expand once more and recommence the secretion of the sticky fluid. The food thus obtained is of benefit to the pl., though it can live without it. D. is able to live in very poor soil. The extra materials obtained are devoted chiefly to seed-production. If the stimulus produced by the capture of an insect be very powerful, the l. itself may bend into a cup form, and this feature is very marked in some sp., the l. bending almost double over the prey.

The fls. of the Brit. sp. rarely open, but self-pollinate in bud. **Droseraceae** (EP., BH.). Dicots. (Archichl. Sarraceniales; Rosales BH.). 5 gen., 100 sp., Drosera cosmopolitan, the rest more local. Herbs, usu. with perenn. rhiz. and rosettes of l.; Aldrovanda a water-plant. All are insectivorous; Dionaea and Aldrovanda have sensitive l. which shut up when touched, the others catch their prey by sticky tentacles upon the l. (see genera). Fls. usu. incinni, rarely in racemes or sol., §, reg., 5—4-merous, usu. hypog. K (5); C 5, imbr.; no disc; A usu. 5, pollen in tetrads (cf. Ericaceae); G (2, 3, or 5); plac. usu. parietal, rarely axile or free-central; style long; stigmas simple or branched; ov. 3—∞, anatr. Loculic. caps.; seed with endosp. and small basal embryo. Genera: Dionaea, Aldrovanda, Drosophyllum, Drosera, Roridula.

Drosophyllum Link. Droseraceae. D. lusitanicum Link, Morocco, Portugal, S. Spain. The l. have glands of two kinds—stalked, secreting a sticky fluid (cf. Drosera), and sessile, which only secrete when stimulated by nitrogenous matter, and then secrete a digestive ferment. Insects alight on the glands and are entangled; they struggle for a while and finally sink down and die, and are digested by the ferment. The taller glands have no power of movement, but are able to secrete a ferment as well as the sessile ones.

Drudea Griseb. Caryophyllaceae (I. 3). 1 Peru.

Drudeophytum Coulter et Rose (Arracacia p.p.). Umb. (111. 4). 5 N. Am.

Edible products, or foodstuffs in a wide sense, are obtained esp. from stores of reserves in pl., e.g. the seeds of cereals, Avena (oat), Coix, Eleusine, Euchlaena, Hordeum (barley), Oryza (rice), Panicum (millet), Paspalum, Pennisetum (bulrush millet), Secale (1ye), Setaria, Sorghum (Guinea corn), Triticum (wheat), Zea (maize), Zizania, &c.; the seeds of many Leguminosae, e.g. Arachis (peanut), Cajanus (cowpea), Cicer (chickpea), Dolichos, Glycine (soy), Lathyrus, Lens (lentil), Phaseolus (beans, &c.), Pisum (pea), Psophocarpus, Vicia (bean), Voandzeia, &c.; the seeds of Araucaria, Bertholletia (brazilnut), Brosimum, Carya, Caryocar, Castanea (chestnut), Castanospermum, Cocos (coconut), Corylus (hazelnut, filbert), Dioon, Fagopyrum (buckwheat), Juglans (walnut), Lecythis, Nelumbium, Pistacia (pistachio), Telfairia, Trapa, &c.; the underground reserves of Allium (onion, &c.), Alocasia, Araceae, Arracacia, Arum, Beta (beetroot), Brassica (turnip, &c.), Canna, Colocasia (taro), Commelina, Daucus (carrot), Dioscorea (yam), Helianthus (Jerusalem artichoke), Ipomoea (sweet potato), Manihot (cassava, tapioca), Maranta (arrowroot). Ophiopogon, Oxalis, Pachyrhizus, Peucedanum (parsnip), Plectranthus, Priva, Raphanus, Scilla, Scorzonera, Selinum, Stachys, Solanum (potato), Tragopogon, Tropaeolum, Ullucus, Xanthosoma, &c.: from reserves in the stems of many trees, esp. palms, Acer (sugar), Alsophila, Arenga (sugar), Borassus (sugar, sago), Caryota (sugar, sago), Cycas, Cocos (sugar), Encephalartos, Metroxylon (sago), Oreodoxa, Saccharum (sugar), &c.; from reserves in l. and infl. in

Brassica, Cynara, many palms, &c. Other l. are also eaten, e.g. Apium (celery), Ceratopteris, Chenopodium, Crambe (sea-kale), Eremuius, Foeniculum (fennel), Lactuca (lettuce), Lepidium (ciess), Myrrhis, Rheum (rhubarb), Scorzonera, Spinacia (spinach), Tetragonia, &c.; similarly the young shoots of Aspaiagus, Bambusa, &c.

This leads on to condiments or spices (see Condiments).

Many fleshy fr. are also eaten; the greatest food value attaches to Artocarpus (bread-fr., jak), Musa (banana, plantain), and Phoenix (date), but others are Aberia, Achras, Anacardium (cashew), Ananas (pine-apple), Anona (custard-apple, &c.), Artabotrys, Averrhoa, Bactris, Benincasa, Blighia, Borassus (palmyra palm), Byrsonima, Carica (papaw), Celtis, Cereus, Chrysobalanus, Chrysophyllum, Citrullus, Citrus (orange, lemon, &c.), Coccinia, Coccoloba, Cucumis (melon, cucumber), Cucurbita (pumpkin, marrow), Debregeasia, Decaisnea, Dialium, Diospyros (kaki), Durio (durian), Eriobotrya (loquat), Eugenia (rose-apple, &c.), Feronia, Ficus (fig), Fragaria (strawberry), Garcinia (mangosteen), Gaylussacia (huckleberry), Glycosmis, Hymenaea, Juniperus, Lantana, Lapageria, Litchi (litchi), Macadamia, Maclura, Mammea, Mangifera (mango), Mimusops, Monstera, Morus (mulberry), Myrtus, Nephelium (rambutan), Opuntia (prickly pear), Osmanthus, Pappea, Passiflora (granadilla, &c.), Pereskia, Persea (avocado), Peumus, Prunus (plum, cherry, apricot, peach, &c.), Psidium (guava), Punica (pomegrana e), Pyrus (pear, apple, &c.), Ribes (gooseberry, currant), Rubus (raspberry, &c.), Sechium, Spondias, Tamarindus (tamarind), Vaccinium (cranberry, bilberry, &c.), Vitellaria, Vitis (grape), Zanthoxylum, Zizyphus, &c.

Drinks (q.v.), and Alcohol), narcotics (q.v.), &c may also be mentioned here. For food for animals cf. Fodder, and Bee-flowers.

pasture grasses for sandy soil.

Eichhornia Kunth. Pontederiaceae. 5 S. Am., W.I. The sympodium is very complex. Each shoot in turn is pushed to one side by the axillary shoot of its last l. but one; with this shoot it is combined, however, up to the last 1. of the axillary shoot. After leaving the axillary shoot, each shoot bears another l., and then ends in the infl., which is enclosed in a spathe, and at first glance appears to spring from the stalk of the last l. In E. azurea Kunth. the fis. are dimorphic, in E. crassipes Solms trimorphic heterostyled. This last sp. has, when floating freely, large bladder-like swollen petioles, but in soil these are not nearly so large. They cause the plant to float high and it is easily blown about by wind, and has become a very troublesome weed (water hyacinth) in Florida, Java, Australia, &c.

Elodea Michx. Hydrocharitaceae. 6 Am.; E. canadensis Michx (American water-weed) arrived in Brit. about 1842 and rapidly spread over the inland waters of Eur. Only the ? plant is known in Eur., and the spreading is therefore due to veg. repr. chiefly by the breaking off of twigs. Submerged pl., slightly rooted, with whorls of l., in whose axils are the usual squamulae. J. fl. P. 6, A. 9; it breaks off as a bud and comes to the surface (cf. Vallisneria), where it opens. The ovary of the ? fl. grows to such a length as to bring the fl. to the surface, where it is pollinated. P. 6, stds. 3, G. (3); enclosed below in

a 2-leaved spathe. The pl. does not form a true winter bud; the l. are merely a little more closely grouped together.

Elongate, drawn out.

Epilobiaceae, Onagraceae.

Epilobium Dill. ex L. Onagraceae (2). 160 temp. and arctic; 9 in Brit. (willow-herbs). Fl. reg., but in some slightly + by the bending of sta. and style, which project and make a landing-place for insects. Of Brit. sp. several may be noticed, as the fls. form a series in regard to cross pollination, &c. In E. angustifolium L. the fls. are large and autogamy almost impossible. Honey is secreted by the upper surface of the ovary. The sta are ripe when the fl. opens, and project horiz., while the style, with its stigmas closed, is bent downwards. Afterwards the sta. bend down and the style up, and the stigmas open. This is the plant in which C. K. Sprengel (1703, see biography in Nat. Science, 1893) made the first discovery of dichogamy. In E. hirsutum L. sta. and stigma are ripe together, but the stigma projects beyond the sta.; if not pollinated it bends back and touches the anthers. E. parviflorum Schreb. is a smallflowered homogamous sp. rarely visited by insects; 4 sta. are shorter, 4 longer, than the style; the former are useful for cross-pollination, the latter for self. The seed has a tuft of hairs aiding windcarriage.

Epiluma Baill. (Chrysophyllum p.p.). Sapotaceae (1). 1 New Caled.

Epimatium, ovuliferous scale (Coniferae).

Epimedium (Tourn.) L. (incl. Vancouveria C. Morr. et Done.). Berberidaceae. 10 N. temp. E. alpınum L. nat. in Brit. It has, like most E., a 2-merous fl., which is pend., with glandular hairs on the stalk. It is protog., and after a time the valves of the anthers bend upwards and roof over the stigma and the 3 stage begins. Finally self-pollination occurs by the elongation of the style carrying the stigma among the valves. The nectaries are of a curious shoe-like pattern. The seeds have a membranous aril.

Epinetrum Hiern. Menispermaceae. 2 trop. Afr. (A).

Epipactis Adans. Orchidaceae (II. 2). 10 N. temp.; 2 Brit, E. latifolia All., and E. palustris Crantz (helleborine). There are two stds. at the sides of the column; the anther is acrotonic. The labellum has a hinged term. portion, which by its rebound causes the insect to fly somewhat upwards in leaving the flr. In so doing it rubs the rostellum, which instantly becomes very viscid and cements the pollinia (which have no true caudicles) to the insect. The chief visitors are wasps. See Darwin's Orchids, p. 93.

Equisetaceae. Pteridophyta (Equisetineae). An order with one surviving genus (Equisetum q.v.), formerly well repres. Many large fossils. Equisetales (Equisetineae). A main division of Pteridophyta (q.v.),

containing the single living fam. Equisetaceae.

Equisetum L. Equisetaceae (only genus). 25 cosmop.; 9 in Brit. (horsetails), chiefly in swampy places. Perenn. herbs with sympodial rhiz. which send up aerial shoots each year, of one or two kinds; in some sp. the ordinary green shoot bears the repr. spike at the end, while in the others there is a special repr. shoot, usu. appearing early in the year, and often without chlorophyll, the ordinary shoots performing assim. work only. The stem is very distinctly jointed, and at the nodes are borne whorls of united 1. closely pressed against the stem, and of little or no use in assim. The branches emerge through the leaf-sheath and thus appear at first sight endogenous; in reality they are exogenous, but formed so much later than the l. that their points of origin are already covered by the leaf-sheath, and so they are compelled to burrow through it. Stages in this process may easily be observed. The surface of the stem is grooved; the ridges are occupied by mechanical tissue, whilst the green tissue and stomata are at the base of the furrows. This is a marked xero structure and is repeated very closely in Casuarina. In several sp. the internodes of the rhiz, are swollen into tubers, which serve for hibernation and

veg. repr.

The spike is very like the & fl. of a Conifer, and has as much right to the title of flower. It is an axis with short internodes, bearing a dense mass of sporophylls. Each is shield-shaped and bears a number of sporangia upon the under side of the head (i.e. towards the stem), arranged like the horses of a 'merry-go-round.' The spores are of one kind only; each has, running round it, two spiral cuticularised bands of membrane, formed from the outer wall and termed elaters. These are hygroscopic, unfolding in damp air. the rolling up again on drying, the elaters of one spore become entangled with those of others and cause them to adhere together, so that several prothalli may be formed near to one another when they germinate. This is advantageous, for the prothalli are dioec, though so far as we can tell the spores are all alike. The prothallus is fairly large, the & being smaller than the ?.

The stems of E. hyemale L. (Dutch rushes) are used for polishing. the mechanical tissues contain much silica, as do those of most.

Equitant (vernation), cf. Vernation.

Eragrostis Host. Gramineae (10). 250 cosmop., mostly subtrop. Eranthemum L. (excl. Pseuderanthemum Radikf.), Acanthaceae

(IV. A). 25 trop. As.

Eranthis Salisb. Ranunculaceae (2). 7 N. palaeotemp. E. hyemalis Salisb. (winter aconite, nat. in Brit.) has a thick rhizome or row of tubers, one formed each year. The sol. term, fls. appear in February, before the l.; each has an invol. of three green l., a 'calyx' of 6 segments, and several honey-1. or petals.

Erica (Tourn.) L. Ericaceae (IV). 500 Eur. (esp. Medit.) and S. Afr. (see fam.). 5 in Brit.; the two common heaths, E. cinerea L. and E. Tetralix L., cover great areas of moor. In habit like Calluna. Fl. bell-shaped and pendulous, visited and fert, mainly by bees. Honey is secreted by the disc, and insects hanging on to the fl. and probing for it must shake the sta. and receive a shower of the loose powdery pollen from the pores in the tips of the anthers. In the wider mouthed sp. the anthers have horn-like projections at the back. which ensure contact with the insect's proboscis. The stigma projects beyond the sta. so as to be touched first.

Many S. Afr. sp. cult. E. scoparia L. is the heath of S. France. &c. (bruyère), several feet high; its rootstocks furnish 'briar' wood

The roots of heaths possess endotropic mycorhiza. Ericaceae (EP., BH. excl. Vacciniaceae, incl. Pyrolaceae p.p., Clethraceae.

Dicots. (Sympet. Ericales EP., BH.). 50 gen., 1350 sp. Owing to their numbers and their social habit they form very char. parts of the veg. in many portions of the globe. Cosmop except in deserts and in hot damp trop. regions. The Ericoideae are confined to Africa, Medit. and Europe, the two great masses of them being however separated by the Sahara, though sp. of Erica, &c. occur in each (see Drude in Nat. Pfl. or Pflanzengeog. for full discussion of the

distr.; also gen., espec. Rhododendron, Vaccinium, Calluna, Erica.) The distr. in moors and swamps, and in peaty soil, is correlated with possession of xero. chars. They are woody, from small undershrubs to large shrubs and even trees, of two types of habit. Encoideae are evergreen with no true winter-buds or scale-l.; the whorled l. are needle-like, often rolled back on themselves to form a groove or chamber on under side (cf. Empetrum). The other tribes usu. form true winter-buds, though the l. may last over winter; the bud is covered with scale-l., which drop as it elongates, leaving a gap on the stem, while the foliage-l. tend to form term. 10settes. L. usu. elliptical, opp, alt., or whorled, exstip., entire or nearly so, leathery, often hally, with strongly cuticularised upper epidermis, and often waterstoring tissue under it. Many are epiphytic.

Infl. usu. term. on strongly growing shoot; a sympodium tends to be formed. Fls. sol., or oftener racemosely grouped, each with br. and 2 bracteoles, \$\frac{4}{2}\$, \$\infty\$ or slightly +. K 4—5, persistent, sometimes accrescent; C (4—5) or 4—5 (Ledeae), usu. bell-shaped; A 8—10, obdipl., hypog. or rarely slightly epipet. or 4—5, anthers intr., often with projecting appendages, the thecae often spreading at top, and opening by apical pores, pollen in tetrads. Below the G is a fleshy disc secreting honey; G (4—5), opp. pets., sup. or inf., 4—5-loc. (2—3 in Sympieza, Tripetaleia, 7 in Befaria), with axile plac. and \$\infty\$ —1 anatr. ov. in each; style simple stigma capitate. Caps., drupe, or berry, usu. \$\infty\$ small seeds; embryo cylindrical in copious endosp.

The fls. of the Brit. sp. are mostly suited to bees by size and hanging position, and have 'loose-pollen' mech. The stigma projects so far as to be first touched, and in probing for the honey at the base of the fl. the bee touches the sta. or their horns, and by shaking them causes the fall of pollen from anther-tips. Calluna is paitly anemoph. Cf. C., Kalmia (explosive), Erica, &c.

[BH. chars. Shubs and trees, I. alt., opp., or whorled, exstip.; usu. persistent. Infl. various. Fls. reg. §. K (4-5) or 4-5; C usu. (4-5), A usu. 8-10, sometimes adnate to base of C, usu. dehisc. by pores; disc various or 0; G (2-12), multiloc. with style and peltate, capitate or lobed stigma; ov. usu. ∞ in each loc., anatr. on axile plac. Caps., rarely drupe or berry, with small seeds. Endosp.] Classification and chief genera (after Drude):

 RHODODENDROIDEAE (septic. caps.; seed with ribbed loose coat, often winged; C falling after fig.; sta. with upright

or long adnate anthers, with no appendages):

Ledeae (polypet.): Tripetaleia (C 3), Befaria (C 7), Ledum (C 5). [Menziesia (included).
 Rhododendreae (+): Rhododendron (sta. exserted),

3. Phyllodoceae (\bigoplus): Leiophyllum (C free, racemes), Loiselcuria (A 5, caps. 2-3-valved), Kalmia (anthers held in hollows of C), Phyllodoce (A 10 free, C bell-shaped), Bryanthus (A 8, C deeply divided), Daboecia (do. toothed).

II. ARBUTOIDEAE (berry or loculic, caps.; seed triangular or ovate, not winged; C falling; anthers much folded, with peglike appendages, or prolonged into tubes, shedding the pollen upwards; G sup.):

Andromedeae (dry caps. with small K at base): Cassiope (l. closely overlapping), Leucothoe (plac. apical, C spherical in bud), Andromeda (do., C cup shaped), Lyonia (caps. valve with swollen edge), Epigaea (C salver-shaped, anthers with longitudinal slits).

Gaultherieae (caps. or berry; K fleshy round caps., or leafy; anthers blunt at tip or with two short processes): Gaultheria (K fleshy round caps., anther-loc. 2-pointed), Pernettya (K dry, berry), Chiogenes (berry nearly inf.).

3. Arbuteae (K as small disc at base of beiry or diupe; anthers with two long processes): Arbutus (beiry loc. manyseeded), Arctostaphylos (1-seeded), Arctous (l. annual).

VACCINIOIDEAE (as II, but G inf.):

Vaccinieae (ovary sharply defined from peduncle): Gaylussacia (G to-loc., anthers not spurred), Vaccinium (5-loc., sta. straight, spurred), Disterigma.

Thibaudieae (K decurrent on ov., and going over into peduncle): Agapetes, Macleania, Thibaudia (A (10), horned).

ERICOIDEAE (fr. usu. loculic. caps. or nut; seeds round, not winged; C persistent after fig.; anther with short connective, thecae spreading above, often appendaged):

1. Ericeae (> 1 seed per loc.): Calluna (caps. septicid.), Erica (loculic.; large disc, sepals equal), Macnabia, Philippia.

Salaxideae (1 per loc.); Eremia, Simocheilus, Salaxis.

Ericaceous, heath-like.

Eucalyptus L'Hérit. Myrtaceae. 230 Austr., 2 or 3 Indomal. (blue-gum, iron-bark, stringy-bark, blood-wood, mallee, &c.). One of the most characteristic genera of the Austr. flora, easily known by the oper-culum of the fl. bud. Trees and shrubby trees. Some sp. reach an enormous size; E. regnans F. Muell. is officially recorded as reaching 326 ft. in height and 25 ft. 7 in. in girth at 6 ft., on Mt. Baw Baw near Melbourne (cf. Sequoia). The l. at first formed are often opp. and dorsiv., the later ones alt. and isobil., more suited to the climate. The barks vary much, but being easily recognized, are a valuable aid in the classification. The most common is smooth bark (gum trees) which exfoliates in patches; other kinds are bark scaly all over the trunk (blood-woods, &c.); bark thick and fibrous, the fibres set longitudinally (stringy-barks), or felted; bark hard and furrowed, often black with age (iron-barks). Infl. usu. an umbel which by lengthening of the axis passes to a panicle or corymb. The floral recept. is hollow and becomes woody in the fr. The K is thrown off as a lid when the fl. opens.

On account of their rapid growth and economic value, these trees are now largely cult. in warm climates. Many yield valuable timber, e.g. E. rostrata Schlecht., E. marginata Sm. (jarrah), E. diversifolia F. Muell. (karii), &c.; E. Globulus Labill. (blue-gum) and others yield oil of eucalyptus; others yield oils, kino, &c.

Euonymus L. Celastraceae. 100 N. temp., and S.E. As. E europaeus L., the spindle-tree, in Brit. Several sp. have curious outgrowths of cork upon their stems. The fls. are polygamous and protandrous. On the ripe seed is a bright red fleshy aril, serving in bird-dispersal. The development of the aril may easily be studied by examining seeds of various ages. The wood is used for spindles, pegs, &c., and furnishes good charcoal.

Euosmia Humb. et Bonpl. Rubiaceae (1. 7). 1 Venezuela. Eupatoriastrum Greenman. Compositae (2). 1 Mexico.

Eupatoriopsis Hieron. Compositae (2). 1 Brazil.

Eupatorium (Tourn.) L. (incl. Conoclinium DC.). Compositae (2). 450 mostly Am., a few in Eur., As., trop. Afr. E. cannabinum L., hemp-agrimony, in Brit. Its fls. are largely visited by butterflies.

Euphorbia L. Euphorbiaceae (A. II. 8). 750 chiefly subtrop. and warm temp. (12 in Brit.). They differ very much in vegetative habit. The British sp. of spurge are herbs and so are many others, but shrubs are also frequent. The chief interest centres in those sp. that inhabit very dry places and have consequently a xerophytic habit. Most of these forms closely resemble Cactaceae (q v), and sometimes when not in fir. it is very difficult to decide from the outside appearance whether one has to do with a Euphorbia or a Cactus. The presence of latex of course distinguishes the former. It is very interesting to see how similar conditions of life have called forth, in three different fams, not nearly allied to one another, such a similarity of habit as is seen in Euphorbia, the Cactaceae, and Stapelia (Asclepiadaceae). As in the cacti, we get almost spherical forms, ridged forms, cylindrical forms, &c. Many are armed with thorns. In all cases it is the stem which is fleshy. The outer tissue is green and does the assimilating work of the plant; the inner portion of the stem consists mainly of parenchymatous storage tissue.

For morphology cf. Goebel (Pflanzenbiol. Schild. p. 56). He

divides the pl. into the following groups:

I. L. normal, well developed, serving a long time as assim. organs. (1) Shoot not water-storing: e.g. the British sp. (2) Storage in tubers below ground: E. tuberosa L. (3) Stem as reserve for water, &c., but not green: E. buplcurifolia Jacq. (cylindrical stem covered with corky scales = 1. bases; 1. borne in wet season, drop in dry). (4) Stem fleshy, green, leafy in wet season only: E. neriifolia L., &c.

II. L. abortive, dropping off early. Assim. and storage carried on in stem. Various types occur here (cf. Cactaceae) approaching ± nearly to perfectly spherical form. Some common ones are (1) E. Tirucalli L. (Zanzibar), with thin cylindrical shoots. E. pendula

Link is very similar and resembles Rhipsalis in Cactaceae. (2) E. xylophylloides Brongn. has flattened shoots (cf. Phyllanthus § Xylophylla, and Epiphyllum in Cactaceae). (3) E. Caput-Medusae L. has a stout stock giving off a number of thinner branches at the top. These are covered with little cushion-like papillae, closely crowded, which are really l. bases; the l. proper is undeveloped. Many sp. show this structure. (4) E. mamillaris L. has a thorn in the axil of each cushion (=a metamorphosed infl.-axis). If the cushions, as in the cacti, become 'fused,' we get a ridged stem, as is seen in (5) E. polygona Haw. (cf. Echinopsis cereiformis in Cactaceae), E. grandicornis and many others. Most of these sp. exhibit pairs of stout thorns which are the stips, of the abortive 1. By the two horizontal thorns one can tell one of these pl. from a cactus, which has a group of thorns. (6) E. meloformis Ait is nearly spherical but ribbed, whilst in (7) E. globosa Sims (cf. Echinocactus) we have an almost perfect sphere. [Cf. Cactaceae, and Stapelia, and compare all these succulent forms with one another. See also Goebel, loc. cit.]

Besides the above, note E. splendens Boj. and E. Bojeri Hook., pl. with thick stems and green l., the latter dropped in the dry season.

The other chief point of interest in E. is the cyathium, or infl. condensed to simulate a single fl. The resemblance is almost perfect. The general branching of the plant is cymose (dichasial). The partial infl. forms a cyathium by the non-development of its internodes, the absence of the P of the individual fls. and the reduction of each & fl. to one sta. There is a perianth-like organ of 5 l., really bracts, and between these are 4 curious horn-like bodies (U-shaped in fig.),

which are the combined stips. of the bracts. Then follow a number of sta. arranged with the oldest nearest to the centre and each with a peculiar joint half-way up the stalk. In the middle of the cyathium is a 3-carpelled ovary on a long stalk, usu. ripe for pollination before any sta. ripen.

That this cyathium is an infl. and not a fl., consisting of a lot of & fls., each of I sta., round a single ?, is shown by the centrifugal (cymose) order of ripening of organs, and the joint on the sta.; at this point in the allied gen. Anthostema, there is a P, which shows that the sta. is really a reduced & fl.

Diagram of central cyathium of infl. of Euphor bia Peplus L. (after Eichler, modified).

In E. § Poinsettia the infl. is rendered conspicuous by the bright red colour of the larger upper bracts. These sp. often cult. orn. infl. The fruit explodes when ripe; the carpels split off from the central

axis and open at the same moment.

Euphorbiaceae (EP., BH. incl. Buxaceae). Dicots. (Archichl. Geraniales; Unisexuales BH.). 220 gen., 4000 sp., cosmop., except arctic. Few sp. have a very wide range; the most widely-ranging genus is Euphorbia. Closely related to Geraniales by the structure of the gynoeceum, &c., although separated a good deal from the other fams. of the order by the amount of reduction in most of its fls.

Most are shrubs or trees, a few herbaceous (e.g. the Brit. sp.). Many are xero; a number of Australian sp. are of ericoid habit; several, esp. S. Afr., Euphorbias are cactus-like; others resemble Lauraceae, or possess phylloclades (e.g. Phyllanthus sp.). A few are lianes. L. usu. alt.; some have opp. l., some opp. l. above and alt. below. Stips. usu. present, but may be repres. by branched hairlike bodies (Jatropha), glands, or thorns. Nearly all contain latex in

special laticiferous cells.

Infl. usu. complex; almost every type occurs. Often the first branching is racemose and all subsequent ones cymose. In some cases, e.g. Dalechampia and Euphorbia (q.v.), the partial infls. are so condensed as to give the appearance of single fls. The fls. are always unisexual, monoec. or dioec., reg., hypog. The P may be present as two whorls usu. 5-merous; more often there is only one (calyx) and frequently the fl. is naked. Sta. 1-0, free or united in various ways. Ricinus has branched sta. Phyllanthus cyclanthera has the sta. united, with a ring-like common anther. G usu. (3), with axile placentae, and 3 loc. Styles usu. 2-lobed. The ovules are constant throughout the family and form its best distinctive feature; they are I or 2 in each loc., collateral, pendulous, anatropous, with ventral raphe. The micropyle is usu, covered by a caruncle, which is also found on the seed. The fruit is almost invariably a 'schizocarp-capsule.' It splits into cpls. often elastically, and at the same time each cpl. opens ventrally, letting the seed escape. See albuminous. [BH. chars. incl. those of Buxaceae, esp. dorsal raphe, and loculic, caps, or drupe.]

Most E are poisonous. Several are important economic plants, e.g. Manihot (rubber, cassava), Hevea (rubber), Croton, Ricinus, &c.

Classification and chief genera (after Pax):

A. PLATYLOBEAE (cotyledons much broader than radicle):

I. PHYLLANTHOIDEAE (ovules 2 per loc.; no latex):

1. Phyllantheae (embryo large, little shorter than endosp.; & calyx imbricate): Phyllanthus.

2. Bridelieae (do., but & calyx valvate): Bridelia.

- 3. Daphniphylleae (embryo short, 4-6 times shorter than endosp.): Daphniphyllum.
- II. CROTÓNOIDEAE (ovules 1 per loc.; latex usu. present):

1. Crotoneae (sta. bent inwards in bud): Croton.

- Acalypheae (sta. erect in bud; fl. usu. apetalous; & calyx valvate; infl. a raceme, spike, or panicle, axillary or term.): Mercurialis, Acalypha, Ricinus, Dalechampia, Tragia.
- 3. Jatropheae (do.; infl. a dichasial panicle): Hevea, Jatropha.

. Adrianeae (do.; infl. a simple term. spike or raceme):
Manihot.

5. Cluytieae (& calyx imbr.; & fls. with petals, in groups or cymes, these partial infls. axillary or in complex infls.):
Codiaeum, Cluytia.

6. Gelonieae (do. but apetalous): Gelonium.

 Hippomaneae (do.; apetalous; infl. axillary or term., spikelike, the partial infl. cymes): Stillingia, Hura, Hippo8. Euphorbieae (cyathium): Anthostema, Euphorbia.

B. STENOLOBEAE (cotyledons as wide as radicle):

PORANTHEROIDEAE (ovules 2 per loc.): Poranthera. II. RICINOCARPOIDEAE (ovules 1 per loc.): Ricinocarpus.

Floral diagrams of Castanea vulgaris, after Eichler. A, diagram of δ cyme in axil of catkin-leaf, the sta. and rudimentary gynoeceum only shown in the first fl. The sequence of the fls. is indicated by the figures 1, 2, 3. B, diagram of φ partial infl. δ = bract, $\alpha \beta$ = bracteoles, $\alpha' \beta' \alpha_i \beta_i$ = bracteoles of second order.

S. Austr. Most are trees with simple 1. and scaly stipules that drop off as the 1. expand. The fls. come out in the axils of the 1. of the current year and are diclinous and anemoph., arranged in catkins or small spikes (exc. Fagus δ). In general there is a close resemblance to Betulaceae, and, as in that fam., the fls. are usu. in dich. cymes in the axils of the catkin-1.; there are often, however, > three fls.

P bract-like, (4-7). d fl. with as many to twice as many or ∞ sta. undivided, with or without rudimentary style. 2 fls. usu. in dich. of 3 in Castanea, 2 in Fagus, 1 in Quercus, &c. G usu. (3) with 3 styles (exc. sp. of Castanea); loculi 3, usu. visible before fert. Plac. axile, each bearing 2 pend. anatr. ov. with 2 integuments. Fr. a

1-seeded nut. Seeds without endosp.

The group of nuts is surrounded by a cup-like organ termed a cupule; in the oak there is one nut in each cupule, in the beech two, in the chestnut three. About the morphology of this organ there has been much discussion. Eichler (see diagram above, fig. B, and Bluthendiagr.) regards it as the combined bracteoles $\alpha' \beta' \alpha_i \beta_i$, Pranti (Engler's Bot. Jahrb. VIII. 1887) as an axial outgrowth. See also Celakovsky in Pringsheim's Jahrb. XXI. 1890, and cf. Betulaceae. The cupule only becomes clearly visible after fert.

Cf. D. xii.

Some of the F. show signs of peculiar development of the embryo-

sac, and other interesting features (see Chalazogamae).

The order includes several important economic plants, chiefly valuable for their timber, e.g. oak (Quercus), beech (Fagus), chestnut (Castanea), &c.

Classification and genera (after Prantl):

Fageae (fls. in dich., rarely sol. in axils of foliage-l.; lat. and single fr. 3-angled): Fagus (& fl. sol. or in dich. of 3; ? in 3 or sol.): Nothofagus (& in dich. of many; ? in 2s).

Castaneae (? fls. in dich. or single in the axils of catkin-l.;

fr. rounded at sides):

Style cylindrical, with pointed stigma, & catkins erect.

Cupule with spines or hard papillae.

Castanea. Cupule with scales. Pasania. Style various, crowned by stigma, & catkins pend. Ouercus.

Fagales (EP.), the 11th order of Dicots. Archichlamydeae. Fagara L. (Zanthoxylum BH.). Rutaceae (1). 140 trop.

Fagelia Neck. Leguminosae (III. 10). 1 S. Afr.

Fagelia Schwencke = Calceolaria L. (Scroph.).

Fagonia Tourn. ex L. Zygophyllaceae. 20 Medit., S. Afr., Calif., Chili.

Fagopyrum Tourn. ex Hall. Polygonaceae (II. 2). 4 As. Fls. like Polygonum, but heterosyled, with long and short-styled forms. F. esculentum Moench. (buck-wheat) largely cult., esp. in N. Am., for its fr. (seed), in which there is a floury endosp. Also used as green fodder, and a good honey-plant.

Pagraea Thunb. Loganiaceae. 20 E. Ind. to Austr., often epiphytic.

Some sp. have nectaries at the outside of the base of the fl. Faguetia L. Marchand. Anacardiaceae (3). 1 Madag.

Fagus (Tourn.) L. (BH. incl. Nothofagus Blume). Fagaceae (1). 4 N. temp. F. sylvatica L. (beech, Brit. and large parts of Eur.) often forms homogeneous forests, and is accompanied by a peculiar undergrowth, e.g. Asperula odorata, Lathrea squamaria, &c. & fls. in pendulous cymose heads, ? in pairs; each cupule encloses two nuts. The wood is hard, and much used in the arts; an oil is expressed from the nuts. Beech hedges in many districts; when growing low it does not drop its l., as it does when it takes the tree form, and thus affords good shelter in winter. A variety with red sap in the cells of the epidermis (copper-beech) is often cult. The beech only flowers every few years, and saves up material in the interval (cf. Agave).

Ficoideae (BH.) = Aizoaceae.

Ficus Tourn. ex L. Moraceae (II). 800 warm, chiefly E. Ind. and Polynes., &c. Trees and shrubs of the most various habit. In general alt. entire 1. with stips. which envelope the bud (acting as a protection to it against heat, &c.) and soon after their unfolding drop Adv. roots are very common.

F. elastica Roxb. (indiarubber tree) grows as a stout independent tree, usu. commencing epiphytically, and often reaching a great size. At its base are developed buttress roots, radiating out in all directions; their depth is often several feet, while their thickness is only a few inches. From the branches are given off adv. roots which grow downwards and enter the soil. These grow in thickness and form great pillars supporting the branches. The l. are entire, and leathery, with a glossy surface. The stips. protect the bud. Rubber is obtained by tapping (cf. Hevea).

F. indica L. and F. benghalensis L. (banyan) show similar habit. The aerial roots form supporting pillars, and by their means the tree may reach immense size. (The banyan is sacred in India; the young roots are provided with tubes of bamboo to protect them, and the ground is prepared for them.) See plate in Nat. Pfl. of the famous

tree at Calcutta.

F. religiosa L. (Peepul or Bo-tree) is similar, but its I. have a long acuminate apex, combined with an easily wetted surface. From the apex (drip-tip) the rain drips off rapidly after a shower and the l. is soon dry. In very wet trop, forests this property is of some importance.

F. Sycomorus L. (sycomore or mulberry fig) N. Afr. and F. Carica

L. (fig) Eur., Medit., are also erect trees.

F. repens Rottl. is a small climbing sp. which takes hold of its support by aerial roots (as in ivy); these secrete a gummy substance containing caoutchouc, and then absorb the fluid constituents, leaving the caoutchouc as a cement, fastening the roots to their support (Darwin, Climbing Plants, p. 185). F. Thwaitesti Miq. and other climbing sp. are heterophyllous, the l. on the climbing shoots small

and different in shape.

F. Benjamina L. and other sp. climb up other trees giving off aerial clasping (negatively heliotropic) roots which surround the trunk. These roots thicken and unite into a network and finally often strangle the 'host' altogether. These sp. often become epiph. by the dying away of their lower portions, but like the Aroids they maintain communication with the ground by long aerial roots. Sometimes they commence as epiphytes and send down aerial roots to the soil.

The infl. is hollowed out, and consists of a number of fls. inside a pear-shaped common recept., which opens by a narrow mouth at the top. Within the mouth, in most, are the & fls., while the rest of the cavity is filled with ? fls. (Sachs, Physiol. p. 434). The & has a P and 1 or 2 sta., the ? a smaller P. Infl. as a whole protog.; mode of pollination extraordinary (cf. Yucca), there being a special insect (Blastophaga, a small wasp) adapted to Ficus fls. The gravid ? enters a fig infl. and lays eggs in the ovary; the & wasps thus formed fertilise the ? s and these as they emerge are pollinated by the & fls. and carry the pollen to new figs. For further details and an account of the peculiar process of 'caprification,' see Müller's Fert. of Fls. p. 521, Nat. Pfl., Cunningham on F. Roxburghii (rev. in Bot. Centr. 45, p. 344), and papers in Bot. Jahrb. II. 1890, p. 245.

Many sp. bear the fis. on old parts of the stem (cauliflory). Fr. multiple, composed of a lot of drupes inside the common fleshy

recept.; that of F. Carica L. is the common fig.

Lac (shellac, &c.) is produced on several by the punctures of a small hemipterous insect (cf. Butea). Several, esp. F. elastica Roxb., yield caoutchouc. The buttress-roots are used as planks.

Filtcales. One of the main divisions of Pteridophyta, char. by well-developed l. with vigorous growth, often large and much-branched; stem usu short in proportion to the l. area, and not much branched. Sporangia borne on the l., usu very numerous.

Classification (after Engler):

- I. FILICALES LEPTOSPORANGIATAE. Sporangia from single superficial cells; prothallus above ground, usu. flattish (see below).
 - . Eufilicineae.
- s. Hydropterideae.

. MARATTIALES. Sporangia from cell complex; prothallus

flattish, antheridia on both sides, archegonia below.

3. OPHIOGLOSSALES. Sporangia from cell complex; prothallus wholly or partially subterranean, tuberous or cylindrical with sunken antheridia and archegonia; embryo often long subterranean. Fertile l. with branches bearing the sporangia.

For further details see next art., Pteridophyta, and the families. Cf. also Nat. Pfl.; Hooker and Baker, Synopsis Filicum; Christensen, Index Filicum (for nomenclature); Christ, Die Farnkrauter der Erde, 1897; Bower, papers on morphology and phylogeny in Phil. Trans. and Ann. Ind. of the last 25 years, and Ferns. Cambridge, Origin of a Land Flora, &c; Seward, Fossil Botany, &c., &c.

Filicales Leptosporangiatae. The first order of Filicales, grouped

as follows:

Sub-order 1. EUFILICINEAE. Sporangium wall usu. with a special ring or annulus of thickwalled cells, by whose means it opens; homosporous, with mono- or di-clinous prothalli.

Hymenophyllaceae: herbs with mesophyll usu. one cell thick,

and marginal sori term. on naked veins.

2. Cyatheaceae: usu. tree or large ferns, with complete and oblique annulus.

3. Polypodiaceae: usu. herbaceous, with imperfect, vertically

placed annulus, not closed at base, rarely absent.

4. Parkeriaceae: water ferns, sporangia sol. on anastomosing veins, almost spherical, with ± perfect, sometimes wanting, vertical annulus, and no true indusium, but inrolled 1. margin.

5. Matoniaceae: herbs with dichotomous l., sporangia with complete oblique annulus, grouped at base of umbrella-like

indusium.

6. Gleicheniaceae: herbs with l. repeatedly dichotomous, and sporangia with equatorial annulus; sori on the veins below.

 Schisaeaceae: mostly small herbs with sessile sporangia, with complete annulus at apex, sol. on l. margin or in axils of bractlike segments.

8. Osmundaceae: short-stemmed ferns with sterile and fertile 1. and naked sori, sporangia with annulus at one side of apex.

Sub order 2. HYDROPIERIDINEAE. Sporangia usu. many in sori, enclosed in metam. l. segments or indusium-like covers; spores of two kinds; macrosporangia with one macrospore, microsporangia with many.

1. Marsiliaceae: sporocarps pluriloc.; sori 2-0 in l. apex, s and ? mixed; ? prothallus with one archegonium, s of one

veg. cell and 2 antheridia.

2. Salviniaceae: sporocarps uniloc.; sori unisexual, on special water 1. (Salvinia) or submerged lobes of water 1. (Azolla); 9 prothallus with a few archegonia, 3 as in Marsiliaceae.

1. Euflicineae. These plants with the Marattiaceae are generally known as Ferns. An outline of the general life history will be found under Pteridophyta.

The fertilised ovum on the prothallus developes directly and without any resting period into a fern-plant. There is no intermediate period of rest as there is in flowering-plants when the seed is ripe. The prothallus continues to assimilate food and supply the young fern until the latter is able to do so for itself. The primary root remains small or withers away, and new ones are adv. formed from the stem or from the 1. bases, as the pl. grows. The mature pl. may be of almost any size from the tiny filmy ferns (Hymenophyllum) to the large tree ferns (e.g. Cyathea, Alsophila). The stem grows by an apical cell, 2- or 3-sided, cutting off segments alt. on each face. From these by further divisions arise the tissues and members. The 1. form a little way behind the growing apex as in fl. pl. One segment (but not every one) gives one l.; the l. grows by an apical cell also. The stem may be erect, or may climb (as in many epiph.), or creep on the surface, or below it as a rhiz. Its growth is slow and branching infrequent. The l. are borne upon it, the internodes being as a rule short in erect, long in creeping stems. The phyllotaxy is not so definite as in fl. pl., but the l. are very commonly in ranks or straight lines dependent on the position of the segments cut off from the apical cell of the stem. The lat. buds arise either on the l. (as in Dryopteris, § Nephrodium) or on the stem; in the latter case they are rarely axillary; but usu beside the l. The growing tips of stem and l. are often protected by brown scales, which are mere trichomes or superficial outgrowths.

The l. is usu. large with apical growth and circinate (coiled) vernation. The growth often lasts for a long time, or even permanently (Lygodium). The l. blade is usu. branched pinnately.

The repr. organs are borne upon the l. The unit is the sporangium or spore capsule, a small rounded body, stalked in fams. 2, 3 and 8 but sessile in the others. The caps. has a wall one cell thick, and in this is a group of cells with peculiarly thickened cell-walls, termed the annulus, by whose agency (its cells being hygroscopic) the opening of the sporangium is effected. Sometimes, as in many Polypodiaceae, the opening is explosive. The mech is in principle similar to that by which anthers dehisce. The annulus may have various forms (see fams.), but the commonest is that of a row of cells running round the sporangium for about § of its circumference.

The sporangia are usu. collected into groups (sori). The sorus may be naked, but is more usu. covered by an industium, sometimes merely a fold of the l. itself, but more commonly a special outgrowth from the l., either epidermal or derived from the more deeply placed layers of tissue as well. The sori are usu. found on the veins of a l., often in the angle where a vein forks They do not as a rule occur on all the l. Very often certain l. are fertile, the others not. In this case the fertile l. have usu. no green tissue at all, their pinnae being entirely covered with sori, e.g. Osmunda sp. In other cases, e.g. Aneimia sp., one part of a l. is sterile, the other fertile. Or again the sori, and this is most common, may be borne simply on the ordinary l. They are almost always on the lower surface only; they may entirely cover it, but more often are localised.

The spores are all of one kind and if sown under suitable conditions give rise to *prothalli*, flat green expansions living for a short or long period independently upon the soil (numbers may be seen where ferns are growing). On the under surface are borne the repr. organs antheridia (3) and archegonia (3). The spermatozoids swim to the ova in the water which collects under the prothalli. The fert. ovum

developes directly into a new fern-pl.

Two interesting modifications of the life cycle as above described are known. In *Pteris cretica, Dryopteris Filix-mas, Aspidium falcatum* and *Todea africana*, there occurs *apogamy* or the omission of the sexual process from the life-history (see diagram in Pteridophyta). The new fern-plant is produced from the prothallus by a process of budding; a growing point developes from the cells of the prothallus. The cycle thus runs:

The other case, apospory, is found in Athyrium Filix-foemina var. clarissima, and in Polystichum angulare var. pulcherrimum, &c. Here spore-formation is replaced by a process of budding which gives rise to prothalli on the backs of the l., so that the life-cycle runs

The latter must not be confused with the 'vivipary' of Asplenium bulbiferum, &c., where the leaf-tissue buds directly into new pl., which for a time remain attached, but ultimately grow independently

(cf. Bryophyllum, &c.).

A very large number of ferns are shade- and moisture-loving plants. Many however are xero and alpine forms with reduced transpiration, exhibiting the familiar char. of such plants—reduced surface, thick cuticle, hairiness, incurving of leaves (ef. Ericaceae), and even, though rarely, succulence (Polypodium adnascens, Drymoglossum carnosum, &c.). The tree ferns and many others have water storage tissue in the stem. Many are epiphytic, esp. in the trop., though they may be found growing in this way even in Britain. Cf. Platycerium, Polypodium, &c. The spores, consisting only of one cell, are much lighter than is possible for a seed, and may be carried by wind to enormous distances.

2. Hydropteridineae or Rhizocarpae. The two fams. of this group, though they have much in common, are probably derived from

different stocks. For details cf. fams.

As in the homosporous forms, so here the embryo gives rise directly to a new leafy pl., usu. aquatic, and exhibiting a creeping stem with a dorsiv. arrangement of the l. Roots may or may not be formed. The stem grows by an apical cell. The sporangia are enclosed in capsular structures termed sporocarps. In the Salv. this body contains one sorus only, in the Mars. more than one. The sorus in the former has one kind of sporangium only, in the latter usu. both. The spores germinate in water; the megaspore gives rise to a small green? prothallus which remains enclosed in the burst spore. Its free surface bears a few archegonia. The microspore gives rise

(sometimes without escaping from the sporangium) to a rudimentary & prothallus and antheridia. From the latter the spermatozoids escape and swim to the 2 organ. Filices, ferns proper, homosporous leptosporangiate Filicales.

Pive-finger (Am.), Potentilla; (W.I.) Syngonium.

Fixed light position, that taken up by l. with regard to light.

Fixed oils, cf. Oils.

Plabellaria Cav. Malpighiaceae (I). I W. Afr.

Flabellate, flabelliform, fan-shaped.

Placourtia (Comm.) L'Hérit. Flacourtiaceae. 15 trop. As., Afr. F. Ramontchi L'Hérit. (Madagascar plum), &c. have ed. drupes.

Placourtiaceae (EP.; Bixinieae p.p., Samydaceae BH.). Dicots. (Archichl. Parietales). 70 gen., 500 sp. trop. and subtrop. trees and shrubs, mostly with alt. stip. leathery l., often ± two-ranked. Fls. sol., axill., or in cymose or racemose mixed infls., often ∞, reg., 4-moremerous, sometimes partly spiral. Peduncle often jointed near base. Axis convex; disc, or glands, scales, &c., between C and A. K 2-15 or (2-15), imbr. or valv., C 15-0, A usu. ∞, sometimes united in antipet. groups, anthers usu. opening by lat. slits; G (2-10) or 1-inf. (inf. in Bembicia), 1- (rarely multi-) loc. with parietal plac. which often project into ov., and sometimes unite; ov. oo, anatr.; styles= plac., or united. Usu. berry or caps.; seeds I or many, often with aril; embryo straight in endosp Some have ed. fr.; a few supply timber, or oil.

Class fication and chief genera (after Engler):

1. Erythrospermae (fl. \(\frac{1}{2}\); P usu. \(\infty\), spiral, A 5-8 with lineal anthers; caps.); Erythrospermum, Berberidopsis.

2. Oncobeae (fl. \(\frac{1}{2}\); K 3-5, C 4-12 imbr., A \(\infty\) with lineal anthers. G (3-10) each with ∞ ov.; fi. not, or late, dehisc.); Oncoba.

Mayna, Carpotroche.

3. Pangieae (dioec.; K 2-5, C 5-8 with scales at base, A ∞ -5, G (2-6) each with ∞-1 ov.; berry or berry-like caps.); Pangium, Hydnocarpus, Gynocardia.

4. Flacourtieae (K 4-6 imbr., C usu. o, A ∞ with short anthers, G as last; berry or caps.); Flacourtia, Xylosma, Azara.

5. Scolopieae (fl. ♥; K 4-6 almost valv., C small or o, A ∞ perig. with short anthers, G (3-6), each with ∞-1 ov., 1- or multi-loc.); Scolopia, Prockia, Banara.

6. Paropsieae (Passiflor. p.p. BH.) (K 5, axis slightly tubular, with disc or gynophore, C 5, often corona, A ∞ -20 or 9-5, perig. or at base of gynophore, sometimes united, G (3-5), usu. with ∞ ov.; palaeotrop.); Barteria, Paropsia.

7. Cascarieae (Samy daceae p.p. BH.) (K 4-5 imbr., C o, A oo or few, sometimes stds., perig., G (2-6), usu. (3), each with ∞ -2

ov.); Casearia, Samyda.

8. Abatieae (Samydac. p.p. BH.) (fl. \(\frac{1}{2}\); K 4, valv., C o, A ∞ -8, perig., no stds., G (2-4) with ∞ ov.; l. opp); Abatia. 9. Homalicae (do. BH.) (K. C 4-15, A 4-15 or ∞ in bundles,

ante-pet., perig. or epig.; l. spiral, rarely paired); Homalium.

10. Phyllobotryeae (fl. g or polyg., K, C 3-5, A 5-∞, hypog., G (2-4), 1-loc. with ∞ ov.; l. alt. with epiphyllous infl.); Phyllobotryum.

Flag, sweet, Acorus Calamus L.; -yellow, Iris Pseudacorus L. Plagellaria L. Flagell. 4 warm | *. Climbers. P. petaloid.

Flagellariaceae (EP., BH). Monocots. (Farinosae; Calycinae BH., pp. v, liv). 3/10 warm | *. Stout stems, sometimes climbing, with long, many-nerved, usu. sheathing l. and panicles; fls., reg., \(\varphi \) or $\varphi \$?. P homoclam., 3+3, A 3+3, G (3), 3-loc. each with 1 axile anatr. ov. Fr. 3-loc. or with 3-1 stones. Endosp. Chief genus Flagellaria. Flagenium Baill. Rubi. (1.8). 3 Madag.

Plomosia Rafin. = Verbascum Tourn. (Scroph.). **Plora**, a catalogue of the pl. growing in a country.

Floral (cf. also under Flower) diagram (cf. those given here under many fams.), an imaginary section through the bud, showing the arrangement of parts, aestivation, &c.; it may also be used (cf. Polygonaceae) to express theoretical views as to multiplication or suppression of organs. At the top is the original stem upon which the fl. is a branch, and at bottom the bract; lat. are the bracteoles; then follow K, C, A, and G, showing their relative positions to one another and to the br. When free they are shown separate; when concrescent, they are joined by lines; the anthers show the mode of opening, the ovary the placentation, stigmas, &c.; -envelope, the perianth; -formula, a convenient way of showing many features of a fl., largely used here. K 3, C 3, A 3, G 3, means calyx of 3 free sepals, corolla of 3 free petals, &c.; ovary superior. K (3), C (3), A 3+3, \overline{G} (3), means calve (corolla) of a concrescent sepals (petals), stamens in two whorls of a each, free, ovary of a concrescent carpels, inferior, and so on; -kingdoms, see Floral Regions; -leaves, the parts of the fl., esp. K and C; -mechanisms, mechanisms to contrive as far as possible cross-fertilisation for a fl., and to ensure that the visiting insect shall receive pollen or touch the stigma, or to ensure They may be classed as follows (see individual self-fertilisation. headings for examples): Anemophily, see Pollination by Wind; Cleistogamy (production of self-fertilising fl.); Dichogamy (ripening of and at different times, with or without movements of sta. and style): Dioecism and other sex-distributions (q.v.); Explosive mechanisms; Heterostylism; Loose-pollen mechanisms; Piston-mechanisms; Pollen-prepotency; Pollination by Animals; Pollination by Water; Pollination by Wind; Self-sterility; Sensitive stamens; Sensitive stigmas; Special mechanisms, such as Asclepiadaceae, Ficus, Orchidaceae, Salvia, Yucca, &c.; Style-projection; Trap Flowers, &c. See Knuth, Handbook of Floral Pollination; Oxford; -regions,

regions char. by the possession of a considerable number of local (endemic) forms; the greater their number, and the higher their systematic rank, the more natural is the region. Engler divides the world as follows: I. Northern Extra-tropical Floral Kingdom, with 9 regions, (1) Arctic, (2) Sub-Arctic or Coniser, (3) Mid-European, (4) Macronesian (Azores, Madeira, Canaries, Cape Verdes), (5) Mediterranean, including land all round that sea, (6) Central Asiatic, (7) Temp. E. Asiatic, (8) Pacific N. Am., (9) Atlantic N. Am.: II. Palaeotropic Floral Kingdom, with 9 regions, (1) N. Afr.—Indian desert, (2) Afr. forest and sleppe, (3) S. W. S. Afr., (4) S. Atl. islands, (5) Madagascar and islands, (6) Nearer India, (7) Monsoonia (warmer Himal., Malaya, N. Austr., Polynesia) (this and 6 are usu. united in this book as Indomalaya, and sometimes called E. or W.), (8) E. China and S. Jap., (9) Hawaiian: III. Centr. and S. American Floral Kingdom, with 5 regions, (1) Mid-American Xero. (S.W. U.S., Mex.), (2) Trop. Am., (3) Andine, (4) Galapagos, (5) Juan Fernandez: IV. Austral Floral Kingdom, with 6 regions, (1) Antarctic S. Am., (2) Antarctic Continental, (3) Kerguelen, (4) New Zealand, (5) Australia, (6) Tristan da Cunha, St Paul, Amsterdam: V. Oceanic Floral Kingdom, with 3 regions, Boreal, Tropical, and Austral; -symmetry shows two chief cases, if radial the fl. is regular or actinomorphic (even if the cpls. be fewer in number), Ranunculaceae, Rosaceae, & c., if not, some members being omitted in the outer whorls, or all members of a whorl not alike, it is irregular and may be zygomorphic (divisible into two halves, each the reflection of the other), Labiatae, Scrophulariaceae, &c., or asymmetrical (not so divisible), Valerianaceae. Cf. Floral Diagram, &c.

Flores verbasci, Verbascum.

Florestina Cass. Compositae (6). 3 Mexico.

Floret, small fl. of a cluster. Floribundus (Lat.), producing many fls.

Plorida Velvet Bean, Mucuna.

Ploridus (Lat.), showy.

-florus (Lat. suffix), -flowered.

Flos (Lat.), a flower.

Ploscopa Loui. Commelinaceae. 15 trop. and subtrop.

Plotovia Spreng. = Chuquiraga Juss. (Compos.).

Flourensia DC. Compositae (5). 10 Arizona to Argentina.

Flower, a repr. short shoot, consisting of an axis (receptacle, q.v., thalamus, torus), bearing essential organs or sporophylls, the androeceum or stamens (q.v.), and gynoeceum or carpels (q.v.), or only one of them in diclinous fl.; also usu. some accessory organs or perianth (q.v.), most often divided into an outer green whorl or calyx, and inner coloured one or corolla; and insects, the relations between fls. and the insects which pollinate them, of. Flower-classes, Floral Mechanisms, &c.; -axis, the receptacle; -bud, the young fl., in which the l. are packed in a definite way (aestivation, q.v.); -classes. the classes into which fis. may be divided according to their relations insects, &c.; W (wind-pollinated), Po. (offering pollen only), A (with freely exposed honey), AB (partly concealed honey), B (fully concealed honey), B' (do. in aggregated infls.), F (Lepidoptera fls. with long tubes), **H** (bee fls. with long tubes, zygomorphism, &c.); see individual classes for examples; colours of - (usu. in corolla) are due to chloroplastids or bodies carrying chlorophyll (rare), Deherainea, chromoplastids or bodies carrying colours, or to coloured cell-sap; all colours change readily to white, and there are several cases of change (q.v.) of one colour to another; bees are inclined to prefer blue, butterflies red and white; -cup, a hollow receptacle; -de-luce, Iris; -description, qf. Description; -, doubling of, change of sta. to petals, or in Compositae of tubular to ligulate fl.; -fence (Barbados), Caesalpnia pulcherrima Sw.; -mechanisms, see Floral; -movements, protecting against cold and wet, e.g. a bending downwards, Anemone, Bellis, Daucus, Fragaria, Linum, Papaver, or a closing of the petals, Anagallis, Bellis, Calandrinia, Eschscholtzia, Tragopogon; -pride (W.I.), Caesalpinia pulcherrima Sw.; -tube, the concrescent portion.

Flowering ash, Fraxinus; -currant, Ribes sanguineum Pursh; -fern, Osmunda; -rush, Butomus umbellatus L.

Fluckigeria Rusby (Kohlerianthus Fritsch, EP.). Gesneriaceae (1).
1 Bolivia.

Flueckigeria O. Ktze. (*Ledenber gia* Klotzsch). Phytolaccaceae. 1 trop. S. Am., W.I.

Plueggea Rich. = Ophiopogon Ker-Gawl. (Lili.).

Flueggea Willd. Euphorbiaceae (A. I. 1). 6 palaeotrop.

Pluegeopsis K. Schum. (*Phyllanthus* p.p. *EP*.). Euphorb. (A. 1. 1). 3 Malaya.

Fluitans (Lat.), floating.

Fluviales = Helobiae.

Fluviatilis (Lat.), growing in streams.

Fly-flowers, Amorphophallus, Araceae, Arum, Asarum, Cobaea, Compositae, Crassulaceae, Cynanchum, Hedera, Helicodiceros, Paris, Stapelia, Umbelliferae, Veronica; -orchis, Ophrys muscifera Huds.; -trap, American, Apocynum; --, Venus', Dionaea muscipula Ellis.

Fockea Endl. Asclepiadaceae (II. 3). 6 Afr.

Fodder. The food of grazing animals, &c. The grasses (fresh or dry) and Leguminosae (esp. the pods) are most generally useful. Innumerable pl. are used in different countries; among the most important are Acacia, Agrostis, Alopecurus (fox-tail grass), Andropogon, Anthoxanthum, Anthyllis, Arachis, Aristida, Astragalus, Atriplex, Avena (oat), Bouteloua (mesquit grass), Brassica, Brisa, Bromus, Buchloe (buffalo grass), Celtis, Cenchrus, Ceratonia (algaroba), Chionachne, Chloris, Chrysopogon, Cicer (chick-pea), Cyamopsis, Cynodon (Bermuda grass), Cynosurus (dog's tail grass), Dactylis (cock's foot grass), Daucus, Deschampsia, Desmodium, Dolichos (horse-gram), Ehrharta, Eleusine (ragi), Eragrostis, Eriochloa, Eruca, Ervum, Fagopyrum (buckwheat), Festuca (fescue), Galega, Glyceria, Gossypium (cotton-seed), Heteropogon, Hippocrepis, Holcus, Hordeum (barley), Imperata, Ischaemum, Lathyrus, Leersia, Lespedeza, Lolium (rye grass), Lotus, Lupinus (lupin), Medicago (lucerne, &c.), Melica, Melilotus, Milium, Mucuna (Florida velvet bean). Muchlenbergia, Musa, Onobrychis (sainfoin), Ornithopus, Orysa (rice), Panicum (millet, Guinea grass, &c.), Paspalum, Pennisetum (bajri), Phaseolus (gram, beans), Phleum (timothy), Pisum (pea), Poa (meadow grass), Secale (rye), Sesamum (gingelly), Setaria (Italian millet), Sorghum (Guinea corn), Spergula, Symphytum, Trifolium (clovet, &c.), Tripsacum, Triticum (wheat), Vicia (vetch), Zea (maize), Zizyphus.

Foeniculum Tourn. ex L. Umbelliserae (III. 5). 4 Medit., Eur., 1 Brit. (fennel). The young l. of F. officinale All. are a good veg. when blanched like celery, and the fr. is a condiment.

Poetid horehound, Ballota nigra L.

Foetidia Comm. ex Lam. Lecythidaceae. 3 Madag., Masc.

Folienia A. Henry et H. H. Thomas. Coniferae (Pinaceae, see C. for gen. char.). 1 E. China.

Folia Jaborandi, Pilocarpus.

Poliaceous, leaf-like, leaf-bearing.

Foliage plants, cult. for orn. foliage, e.g. Begonia, Caladium, Codiaeum, Coleus, many Coniferae, Cordyline, Cortaderia, Dracaena, Eryngium, many Ferns, Fittonia, Gunnera, Gesneria, many Palmae, Panax, Pelargonium, Phormium, Rheum, Rhus, Selaginella, Smilax, Sonerila, many trees.

Folium (Lat.), a leaf; -folius (Lat. suffix), leaved.

Follicle, a dry dehisc. fr. of one cpl., dehisc. on ventral side only; Aconitum, Apocynaceae, Asclepiadaceae, Banksia, Crassulaceae.

Polotsia Costantin et Bois. Asclepiadaceae (II. I). I Madag.

Fruit, the product of that process of growth initiated by the act of fert.; true fr. is the product of ovary only, false fr. or pseudocarp of ovary with any other organ that developes. Simple fr. where the fl. gives one indivisible fr.; aggregate where several similar fr. come from one fl., as in raspberry, buttercup, Ochna, Rubus, &c.; multiple or collective, where several fl. combine to give one fr., as in fig, mulberry, plane. They may be dry or fleshy, may open (dehiscent), or not (indehiscent): some, called schizocarps, break up into one-seeded portions (mericarps).

Dry indeh. fr. are divided into achenes and nuts, the former defined as the product of one, the latter of > one cpl.; but in Ranunculus, Potentilla, &c., but the name is also given to the fr. of Compositae, Gramineae (this variety, with pericarp and testa united, is sometimes called a caryopsis), Labiatae, &c. True nuts, from sup. ov., in Betulaceae, but the term is applied to the large one-carpelled fruit of Anacardium, &c. A var. of achene or nut is the winged one-seeded indeh. samara of ash, elm, Banisteria, Liriodendron, Ptelea,

Seguieria, Ventilago, &c.

Schizocarps various, e.g. the lomentum of many Leguminosae (a pod constricted between seeds, breaking into one-seeded portions), the schizocarps of Euphorbiaceae, Geraniaceae, Malpighiaceae, many

Malvaceae, Sapindaceae, Umbelliferae.

Dry dehisc. fr. of several kinds, esp. the follicle, lexume, and capsule. Follicle of one cpl., dehisc. along ventral side only, Aconitum, Asclepiadaceae, Apocynaceae, Crassulaceae. Legume similar but dehisc. along both sides, as in most Leguminosae. Dry fr. of > 1 cpl. are capsules, but special forms have special names, e.g. the pod-like siliqua of Cruciferae, the pyxis of Anagallis, &c. (capsule opening by a lid split off by circumscissile dehiscence), and others. The way in which it dehisces is of systematic importance. It usu splits from apex down. If the splits, as in Epilobium, Iris, &c., run down the midrib of each cpl., the dehisc is loculicidal: if, as in Hypericum, the fr. breaks into its component cpls., leaving the placental axis standing, it is septicidal; if the outer wall of the fr. breaks away, leaving the septa standing, it is septifragal. The portions into which the fr. splits are termed valves. In some Campanulas,

Papaver, &c., the dehiscence is porous, little openings forming in the

pericarp.

The commonest fleshy fr. are the berry and drupe. The former contains no hard part but the seeds; these are surrounded by fleshy tissue and there is a firmer skin (epicarp) on the outside. Berries may be derived from sup. ovaries, as in Berbetis, Solanum, Vitis, &c. or inf., as in Ribes, Vaccinium, &c. In rare cases the berry dehisces, Akebia, Myristica, or is constricted between the seeds, Maerua, Unona. The drupe (e.g. cherry) has a skin (epicarp) on the surface, then a fleshy mass of tissue (mesocarp) and a hard shell or stone (endocarp), all forming part of the pericarp; within the stone is the seed or kernel, usu. without a hard coat. Drupes from sup. ovaries occur in Prunus, &c., from inf. in Cornaceae, Juglans, &c. There may be one stone or pyrene (Prunus) or several (Cornus).

Other fleshy fr. are the pome of Pyrus, &c. in which the fleshy receptacle encloses, and is united to, the core or product of the G proper; the pepo or gourd of Cucurbitaceae, e.g. cucumber (a variety of the berry with hard epicarp), the peculiar pseudo-berry of Juniperus (q.v.) &c., the fr. of strawberry (fleshy recept. bearing achenes), rose (fleshy recept. enclosing achenes), Anacardium (fleshy recept. bearing nut), Gaultheria (caps. enclosed in fleshy calyx), Urera, &c. (achene in fleshy perianth), and so on. Aggregate-fleshy fr. in Anonacae (berries), Rubus (drupes), &c. Multiple fleshy fr. frequent in Moraceae (e.g. mulberry, fig. bread-fruit), Ananas, Anona, Carlu-

dovica, &c.

The style and stigma often fall away as the fr. ripens, but frequently remain in a \pm shrivelled or in an enlarged condition. Sometimes the style forms a hook, as in Geum, a plume, as in Clematis, or an *awa*, as in Geraniaceae (this name is applied to any long thread-like organ on a fruit; cf. Gramineae).

Other interesting morphological features in fruits: cf. Heterocarpy, Aesculus, Bertholletia, Chenopodium, Leontodon, Nymphaeaceae, Nyctaginaceae, Palmae (e.g. Phytelephas, Lodoicea, &c.),

Genipa (Tourn.) L. Rubiaceae (I. 8). 6 warm Am., W.I.

Genista L. Leguminosae (III. 3). 90 Eur., N. Afr., W. As.; 3 In Brit. G. anglica L. (needle-gorse or petty whin) has large thorns (branches). The fl. has an explosive mechanism, typical of many of the fam. (q.v.). In G. tinctoria L., the dyer's greenweed (Muller's Fert. of Fis. p. 189), there is no honey; the style and tube of sta. are enclosed in the keel, which is united along the top seam as well as the bottom. The sta. shed their pollen almost in the apex of the keel, but not so near it as to pollinate the stigma. When the fl. opens there is a tension of the sta.-tube on the lower side tending to bend it upwards; this is resisted by an opposite one in the keel and wings, but if an insect alight on the wings and press them down, the upper seam of the keel gives way and an explosion follows. In it the style flies out, striking the under side of the insect, thus probably becoming cross-pollinated, and is followed by a shower of pollen which gives the insect a fresh coating to take to another fl.

A yellow dye is obtained from the fls. of this sp., which when

mixed with woad gives a fine green (Kendal green).

Genlisea A. St Hil. Lentibulariaceae. 12 trop. Am. and Afr.

Gentian, Gentiana.

Gentiana Tourn. ex L. Gentianaceae (1). 400 cosmop. exc. Air., chiefly alpine; 5 (gentian) in Brit. Most are alpine pl. of tufted growth. Fls. of interest (see Nat. Pfl., Muller's Fert. of Fls., Alpenblumen, &c.). The genus shows an ascending series of fls., adapted to higher and higher types of insects. G. Intea L. is a primitive type, with freely exposed honey, yellow homogamous fl. and shorttongued visitors. G. purpurea L., G. Pneumonanthe L. (Brit.), &c. are blue long-tubed humble-bee fls. G. verna L. (Brit.), G. Amarella L. (Brit.) and G. campestris L. (Brit.) are long-tubed butterfly fls., sometimes protandr.

The gentians form one of the most striking features of the flora of the Alps, occurring in large masses and with very conspicuous fls.; G. acaulis L. is the most beautiful. In the Brit. Mts. they are rare.

The root of G. lutea furnishes a tonic.

Gentianaceae (EP., BH.). Dicotyledons (Sympet. Contortae; Gentianales BH.). 80 gen., 800 sp. in every part of the globe and in great variety of situations—arctic and alpine pl., halophytes, saprophytes (Voyria, &c.), marsh pl. (Menyanthes, &c.), water pl. (Limnanthemum), &c. They are mostly herbaceous (often perennial); a few shrubs. The perennial herbs have usu. a rhizome. L. opp., exstip., usu. entire. The infl. is usu. a dichasial cyme like Caryophyllaceae; as in that fam., the lat. branches often become monochasial. Other cymose infls. also occur. Bracts and bracteoles present or not. Fls. reg., §, 4—5-merous (rarely more). K usu. (5), imbr.; C (5), bell- or funnel-shaped, or sometimes salver-shaped, conv. (exc. Bartonia, Obolaria, &c., and § 11); A as many as petals, alt. with them, epipet.; anthers various, usu. introrse; G with a glandular disc at base, (2), placed in the antero-posterior plane.

Placentae usu. parietal, but they commonly project far into the cavity and spread out at their ends; occasionally the ovary is 2-loc. with axile plac.; ovules usu. ∞ , anatr.; style simple; stigma simple or 2-lobed. Fr. usu. a septicidal caps. with ∞ seeds rarely a berry (Chironia, &c.); seeds small; embryo small, in abundant endosp.

The flowers of G. are insect-fertilised. The genus Gentiana has

been very fully studied; see also Menyanthes (dimorphic).

Classification and chief genera (after Engler):

Geraniaceae (EP; BH. incl. Oxalid., Limnarth., Tropaeol. Balsamin.).

Dicots. (Archichl. Geraniales EP., BH.). 11/750, cosmop., mostly herbs, often hairy; Sarcocaulon fleshy. L. opp. or alt., often stip. Fl. usu. reg., \$\forall \text{, 5-merous.} \text{ K 5, or (5) imbr. with valvate tips, persistent; C 5, imbr. or conv.; A as many or 2 or 3 times as many as petals, united at base, obdipl. when > 1 whorl, anther usu. versatile; \$\forall (\forall \text{or (2-3) or (3-5), with 1-2 or 2-\infty \infty ovules in each on axile plac.; ovules usu. pend. with ventral raphe and micropyle facing upwards; style long with 5 stigmas. Fls. usu. protandr. Fr. usu. a

schizocarp, the cpls. splitting off from a central beak (the persistent style); each takes with it a strip of the tissue of the style, forming an awn, which is usu. hygroscopic (cf. Geranium, Erodium). Embryo straight or folded, in endosp. Chief genera: Geranium, Erodium, Pelargonium, Sarcocaulon. [BH. chars. Herbs with alt. or opp. l. Fl. \$\frac{3}{2}\$, reg. or \$\dagger\$. Recept. hardly disc-like, often with 5 glands alt. to C. K 5 or less, C 5 or less, or 0, imbr., rarely conv.; A twice as many as K, often \$\pm\$ connate, \$\frac{G}{3}\$—5, rarely 2), multiloc.; ovules \$1\$—2 per loc., pend. or not, raphe various. Caps., schizocarp, or rarely berry. Endosp. little or 0.]

Geraniales. The 23rd order (Engler) of Dicots. (Archichl.). The

7th cohort (BH.) of Polypetalae. Cf. pp. xxii, li.

Geranium (Tourn.) L. Geraniaceae. 300 cosmop., esp. temp. (12 in Brit., incl. G. pratense L., meadow cranesbill, and G. Robertsanum L., herb Robert). Infl. cymose, either dich. with cincinnus-tendency (by preference of the β-bracteole), or a cincinnus alone, which is straightened out into a sympodium. The nectaries are at the base of the sta. These stand at first round the undeveloped style; after dehiscence they move away, and finally the stigmas open. The fr. explodes, the awn twisting up so that the cpls. are carried up and outwards. In many sp. they open at the same time and the seeds are shot out. The G. of greenhouses is really a Pelargonium.

Geranium (of greenhouses), Pelargonium; -grass, -oil, Cymbopogon.

Gesneria L. Gesneriaceae (II). 50 trop. Am., W.I.

Gesneriaceae (EP., BH.). Dicots. (Sympet. Tubiflorae; Personales BH.). 85 gen., 1100 sp. trop. and subtrop., mostly herbaceous or slightly woody; shrubs and trees are rare. L. usu. opp., rarely whorled on alt., entire or toothed, never divided, exstip. Some are root-climbers, and amongst these are a few epiphytes, e.g. Aeschynanthus, usu. with fleshy water-storing l. Many are tuberous, e.g. the Sinningia (Gloxinia) of greenhouses. A number repr. veg. by means of curious runners or suckers, covered with scale-leaves, usu.

formed below ground, e.g. Naegelia, Isoloma, &c. A peculiar morphology and life-history is found in Streptocarpus (q.v.).

Fls. sol. or in cymose infls. of various types, \$\forall \text{, usu. markedly }\forall \text{.} (5), usu. with very stout teeth, generally valvate; C (5), often

2-lipped, imbr. (in Ramondia, &c. it is nearly rotate and reg.); A usu. 4, didynamous, or 2, or 5 (Ramondia, &c.), altwith corolla lobes; stds. often found. At the base of the flower-tube is a disc, whose various shapes form important marks in distinguishing gen.; it may be ring-shaped (thin or thick), 5-angled, 5-lobed, or reduced to 5 or fewer glands. G sup., or ± inf. (see below); always (2), t-loc. with parietal plac. which sometimes project inwards so far that it becomes imperfectly 2-loc.; ovules \infty, anatr.; style simple; stigma often bilobed. Fr. usu. a caps., splitting loculic. into 2 valves, each of

Floral diagram of Gesneria, after Eichler; d=disc-gland.

which may again split into 2; sometimes (Ramondia) the caps. is septicidal, or opens only at the tip, or the fr. may be ± fleshy or berry-like. Seeds small and numerous, with endosperm (§ 11) or without (most of § 1). Embryo straight.

Fls. mostly protandrous; their large size and bright colours suit them to insects. Saintpaulia (q.v.), Klugia, and others exhibit two types of symmetry on the same plant, the fls. (and usu. the l.) on the left side of the infl. being like the reflections of those on the right (enantostyly).

Germin. interesting, esp. in Streptocarpus (q.v.). The cots are epigeal, and usu. thin, one larger than the other and often growing subsequently to some size: buds are often found in their axils. Anisophylly is very common, and usu. alt. on one side and the other.

None of the G. are economic plants; many are hothouse favourites.

Classification and chief genera (after Fritsch):

"The relationships to allied orders, especially Scrophulariaceae, Orobanchaceae and Bignoniaceae, are so close that it is almost impossible to draw the dividing lines. The B. are most sharply marked off by the structure and formation of their fruit and seed, and often by their divided leaves. The O. might very well be placed in G as a parasitic sub-order. The placentation and structure of the ovary is the chief mark of distinction between the G., O., and S."

I. CYRTANDROIDEAE (ovary free, sup.): Ramondia, Saintpaulia, Didymocarpus, Streptocarpus, Aeschynanthus, Besleria, Cyrtandra, Columnea.

II. GESNERIÓIDEAE (ovary more or less inf.): Achimenes, Isoloma, Gesneria.

Gingelly, gingili, Sesamum indicum L. Ginger, Zingiber officinale Rosc. Gingidium F. Muell. = Aciphylla Forst. (Umbellif.). Ginginsia DC. = Pharnaceum L. (Aizo.). Ginkgo L. Ginkgoaceae. 1, G. biloba L. (Salisburia adiantifolia Sm.), the maidenhair tree, perhaps found wild in W. China, but carefully preserved as sacred in temple gardens. It grows in the open in Eur.,

reaching 100 feet; 1. deciduous in autumn, resembling those of maiden-

hair fern, and very often with a deep median division, forked in venation (cf. ferns and cycads), scattered on long shoots, or crowded at the apex of short shoots, which sometimes elongate into long. Below the l. on the short shoot are a few scale l. Fls. dioecious, in the axils of the uppermost scales or lowest green 1. on a short shoot (position different from that usual in Coniferae with long and short shoots). & a stalked central axis, bearing scattered rather loosely disposed sta., each of which is a slender filament ending in an apical scale and two or more pollen-sacs with longitudinal opening. pollen grain forms a rudimentary prothallus of a few cells, and the generative nuclei produce two large spirally coiled spermatozoids (cf. cycads). The ? has the form of a long stalk with two term. elliptical ovules enclosed at the base by a collar-like envelope repres. a reduced carpellary I. Each ov. consists of a nucellus surrounded by one integument, which in the ripe seed forms a thick fleshy arillike covering round a hard woody shell. In the mature ov. the greater part of the nucellus tissue is reduced to a thin papery layer enclosing a large embryo-sac with usually 2 aichegonia. Fert. occurs before or after the ovule has fallen from the tree. The embryo has 2 cots.

The seed is edible, and yields an oil, and the timber is useful.

Ginkgo thus represents a very old type, with relationships to the Cycadales and the Filicales. Fossil species are found in the Carboniferous, Permian, Triassic, and Jurassic, and in the Tertiary of England.

For details see Coulter and Chamberlain, Morphology of Gymnosperms; Fujii on floral morphology in Bot. Mag., Tokio, 1895; Seward and Gowan in Ann. Bot. 1900, p. 108; Ikeno on fertilisation in Ann. Sci. Nat. Bot. XIII. 1901, p. 303; Lyon on embryology in Minn. Bot. Stud. III. p. 275.

Gnetaceae. The only fam. of Gnetales, comprising 3 very distinct gen. with about 45 sp. trop. and subtrop. They are distinguished from the Coniferae by the absence of resin, by the presence of vessels in the secondary wood, and of a P. [Cf. Pearson, Gnetales.] Classification and genera (after Engler):

EPHEDROIDEAE (& P 2, A 2-8 of sessile 2-loc. anthers; ? P pipe-like, ov. with simple integument.

P hard when ripe, br. fleshy): Ephedra.

TUMBOOIDEAE (& P 4, A 6 with 3-loc. anthers; II. 9 P pipe-like, ov. with 1 integument. Stem tuberous with 2 permanent l.): Tumboa (Welwitschia).

III. GNE TOIDEAE (& P tubular, A 2 sessile on thread-like elongated axis; ? P pipe-like, ov. with 2 integuments. Usu. climbing; fls. in spikes, P becoming fleshy): Gnetum.

Gnetales, a class of Gymnospermae; only fam. Gnetaceae.

Gnetum L. Gnetaceae. 35 trop. Most are climbing shrubs, a few erect shrubs or small trees. L. decussate, exstip., simple, evergr., leathery. Fls. dioec., in spikes which are frequently grouped into more complex infls. The spike bears decussate bracts, in whose axils are condensed partial infls. of a large number of firs. (cf. Labiatae), about 3-8 in the 2, but more (up to 40) in the d. These fls. form whorls round the stem, and are intermingled with numerous hair-structures. At the top of each nodal group of the s infl. in most is a single ring of ? fls., usu. with only 1 integument and infertile, sometimes with 2 or even 3 integuments and fertile. The 3 has a tubular (2-leafed) P, from the top of which the axis projects; at the tip of the axis, right and left, are two sessile 1-loc. anthers. The ? has a tubular P like that of Ephedra, surrounding a single orthotr. erect ovule with two integuments; the inner of these projects at the apex of the fl. But there is much difference of opinion as to the morphology of these three envelopes. After fert. the P becomes fleshy, the outer integument woody, forming a drupe-like fr. G. Gnemon L. racemes, or spikes. K usu. 5, small; C (5); A 5, alt. with the petals, epipet. or not, with introrse sometimes syngenesious anthers; G (2), inf. or semi-inf. 1- or 2-loc.; ovules 1, 2, or ∞ in each usually ascending, anatr.; style simple with 'pollen-cup' close under the stigma. Into this the pollen is shed in the bud; it then closes up, leaving only a narrow opening. The style bends down to stand in the mouth of the almost horizontal fl., so that insect-visitors come in contact with the cup and dust themselves with a little of the powdery pollen. As the stigmatic lobes grow up in the cup they keep forcing fresh pollen into the narrow slit, and finally emerge by it themselves and then receive the pollen of younger fls. from insect-visitors. The mechanism should be carefully compared with that of Campanulaceae and Compositae. Fr. usu. caps., sometimes a nut or drupe. Embryo straight, in fleshy endosp.

The G. are very closely allied to Campanulaceae, differing chiefly in the absence of latex and the presence of the pollen-cup. They resemble Gentianaceae in a few points. Chief genera: Goodenia, Leschenaultia, Scaevola, Dampiera. [BH. chars. incl. those of

One of the largest orders of fig. pl., with about 450 gen. and 4500 sp. in all regions of the globe. In the temp, zones esp, they are a most important feature in the veg., forming prairies, steppes, &c. Most grasses are herbaceous with fibrous root, but a few, chiefly the bamboos (a.v.), reach a large size, even as much as 100 ft. Many are annual, but many perennial; the latter commonly branch largely from their lower nodes and thus often give rise to a tufted habit (as seen in many common sp.); many possess rhiz. The stem has well-marked nodes, composed chiefly of softer tissues. If a stem be bent downwards (as occurs when wheat is 'laid') these nodes recommence growth, growing more rapidly upon the lower side, so that the stem is once more brought to the vertical position. The stem is usu. hollow (exc. Zea, Saccharum, &c.) and circular in section. The l. are alt., and with few exceptions, in 2-ranked phyllotaxy: they have a sheathing base, the edges of the sheath overlapping one another upon the side of the stem opp. to the blade (cf. Cyperaceae); there is no petiole (exc. in a few bamboos, &c.), and at the junction of blade and sheath there is a little membranous outgrowth, the ligule, upon the upper side of the leaf. The blade is usu, linear, Many xero, grasses have grooves along the upper side of the l., with the stomata at the bases of the grooves; in most of these cases the

1. rolls up upwards in dry air, enclosing the stomata completely and checking transpiration; the lower surface, which thus becomes the outer, is covered with thick-walled cells and has no stomata. When

the air again becomes moist the l. unrolls.

The infl. is complex; the unit of infl. is not the individual fl. but a spikelet, or small spike of fls. These are well seen in oats. where they are arranged in a panicle; in wheat the spikelets are sessile upon the main axis, forming a cpd. spike, usu. termed simply a spike; this is more clearly seen in rye-grass. Each of these spikelets consists of one or more (usu. not more than 5) fls. one above the other on opp. sides of a very short axis, the whole enclosed in one or two or more larger leaves at the base of the axis, the

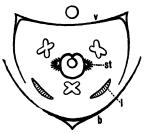

glumes. The first diagram gives a rough representation of the construction of a spikelet. The central line represents the axis (supposed elongated), which bears at the base usu. two leaves with nothing inner glume in their axils; these are the glumes.

inf. palea -- inf. palea inf. palea -- inf. palea - outer glume

Above them stand one or more leaves, the inferior paleae, in whose axils occur fls. (sometimes aborted). Upon the axis of the fl., opp. to the inf. palea, stands another leaf, the superior palea. Between the paleae the fl. itself is enclosed. The sup. palea, being upon the same axis as the fl., is evidently its bracteole. Owing to the shortness of the floral axis, it appears to be in the axil of the inf. palea, or

even upon the main axis of the spikelet. Above the sup. palea are

two very small scales, the lodicules; they are opp. to the sup. palea (I in fig.) and insignificant in size. They are sometimes supposed to repres. two of the three l. of a reduced P. but it seems more probable that they really repres. a second bracteole and that the fl. is perfectly naked. The fl. itself has usu. 3 sta. with long filaments and versatile anthers, and t cpl. forming a 1-loc. ovary, with I basal erect anatr. ovule, and I or more (usu. 2) stigmas, much branched. This ovary has sometimes been regarded as formed of > 1 cpl., but the suture of the post. side of the ovary (cf. Prunus) seems

Floral diagram of a grass (after Eichler). b, inferior palea; v, superior palea; l, lodicule; st., stigma.

to point clearly to its being of 1 cpl. only. The two stigmas may then be regarded as developments of the lat, parts of the cpl. whilst the central part (which usu. forms the stigma) remains undeveloped; this also is the explanation of the two lodicules placed right and left of the proper position for an upper bracteole.

All the fis. in the spikelet are enclosed as a rule within the glumes until ready to open. Then the glumes separate, and the hygroscopic lodicules force apart the paleae of the fis. Most sp. in Eur. are anemoph. and protog.; the sta. grow very rapidly in

warm weather and suspend the anthers clear of the paleae so that the loose powdery pollen is easily blown away and may be caught by the

large stigma of another fl.

The fruit is a caryopsis, i.e. an achene whose pericarp is completely united to the seed-coat. Its construction can be well seen in maize (or wheat); at the broad end is the scar of the style, and on the under side at the pointed end is the embryo; on the upper side is the hilum or point where the ovule was attached to the wall of the cpl. (the form of this scar is important in classification); the bulk of the seed consists of floury endosp. The embryo is straight, with its one cot. (scutellum) completely enwrapping the radicle and plumule (this can be easily made out by dissecting soaked material). The radicle is towards the lower end of the fr. In germin. the cot. remains within the seed and extracts nourishment from the endosperm; afterwards it withers away. Most grass frs. are sufficiently light to be dispersed by wind, esp. as the paleae often remain attached to them and become dry and chaffy. Others have hooks. Self-burying arrangement in Stipa (q.v.), effected by aid of the awn (this term is applied to any long thread-like outgrowth of glume or Many grasses, e.g. sp. of Poa and Festuca, are viviparous, esp. on mountains. The spikelets are replaced by leafy shoots with adv. roots at their bases. These drop off and grow upon the soil (cf. Agave, Allium, &c.).

From the economic point of view the G. are only rivalled in importance, if at all, by the Palmae and Leguminosae. The cereal grasses, e.g. Oryza, Triticum, Zea, Avena, Hordeum, &c. afford food to a large proportion of the earth's inhabitants (see Edible Products). Many grasses are valuable as fodder (q.v.) for domestic animals, or for hay. The bamboos (q.v.) supply many of the wants of the natives of trop. countries, Iapan, &c. Many are used as sandbinders, &c.

Classification and chief genera (after Hackel): the G. show near relationship only to Cyperaceae and perhaps Juncaceae, and are easily distinguished from these sittles but the property of the control o

distinguished from these either by their veg. or floral characters.

A. Spikelets 1-flowered without elongation of the axis beyond the fl., or 2-flowered with the lower fl. imperfect; without measurable internode between the individual glumes or paleae, and when ripe falling off from the stalk as a whole or together with certain parts of the axis of the spike.

a. Hilum point-like; spikelets not compressed lat., but

usually dorsally compressed or cylindrical.

I. Maydeae (inf. palea and, when present, sup. palea thin and membranous; glumes firm, even leathery or cartilaginous, the lowest one the largest and overlapping the rest; spikelets usu. in racemes or spikes which become jointed when ripe; a and ? spikelets in separate infls. or in separate parts of the same infl.); Euchlaena, Zea, Coix.

 Andropogoneae (as I, but spikelets \$, or 3 and \$ side by side in the same infl.): Saccharum, Andropogon, Sorghum.

 Zossicas (paleae membranous; glumes herbaceous, papery or leathery, the lowest usu. the largest; spikelets falling singly or in groups from an unjointed spike-axis): Zoysia.

- Tristegineae (paleae membranous; glumes neroaceous or firm and papery, the lowest smaller or narrower than the rest; spikelets falling singly from the twigs of a panicle): Arundinella.
- Paniceae (paleae usu. cartilaginous, leathery or papery; glumes more delicate, usu. herbaceous, the lowest usu. smaller; spikelets falling singly from the twigs of a panicle or unjointed spike-axis): Paspalum, Panicum, Setaria, Cenchrus, Pennisetum, Spinifex.
 - b. Hilum linear; spikelets lat. compressed.

5. Oryzeae: Zizania, Oryza, Lygeum, Leersia.

- B. Spikelets 1—many-flowered; when 1-flowered often with a prolongation of the axis above the fl., their stalks usu. jointed above the glumes, so that they fall off leaving these on the axis; when 2- or more-flowered, always with distinct internodes between the fls.
 - a. Stem herbaceous annual. No petiole, or joint between blade and sheath.
 - 7. Phalarudeae (spikelets in panicles, spikelike panicles or racemes on distinct stalks—sometimes very short, not set in notches on the main axis; 1-flowered, with 4 glumes and 1-nerved sup. palea): Phalaris, Anthoxanthum.

 Agrostideae (as 7, but spikelets with two or no glumes and 2-nerved sup. palea): Aristida, Stipa, Phleum, Alopecurus, Sporobolus, Polypogon, Agrostis, Calamagrostis, Ammophila, Apera, Lagurus.

9. Aveneae (infl. as 7, but spikelets 2—many-flowered; inf. paleae usu. shorter than glumes, with twisted awn upon the dorsal side, more rarely with no awn or with an awn upon the tip as 10, but then always with 2 almost opp. fls. and no prolongation of the axis beyond them): Holcus, Aira, Corynephorus, Deschampsia, Trisetum, Avena, Arrhenatherum, Danthonia.

 Festuceae (as 9, but inf. palea usu. longer than glume, without awn or with untwisted awn at tip): Sesleria, Gynerium, Arundo, Phragmites, Eragrostis, Catabrosa, Melica, Briza, Dactylis, Cynosurus, Poa, Glyceria, Festuca, Bromus, Problemedium

Brachypodium.

 Chlorideae (spikelets in 2 rows approximated to one another, forming a one-sided spike or raceme with unjointed axis): Cynodon, Spartina, Chloris, Bouteloua, Eleusine.

 Horaceae (spikelets in 2, or rarely more, opp. rows, forming a symmetrical, rarely one-sided, spike): Nardus, Lolium, Agropyrum, Secale, Triticum, Hordeum, Elymus.

b. Stem woody, at least below; leaf often petiolate, finally separating from its sheath by a joint.

13. Bambuseae: Arundinaria, Bambusa, Dendrocalamus.

Space will not permit of giving a key to the genera; the student should work through the commoner ones with a flora, or with Ward or Hutchinson's *British Grasses*.

Gymnospermae. One of the two great divisions of Spermaphyta or

ymnospermae. One of the two great divisions of Spermaphyta or seed-plants, distinguished from Angiospermae by the fact that the cpls. are not so infolded or united as to form an overy round the ovules; also the endosp. (semale prothallus) is formed before fertilisation. The existing G. are divided into four great classes, Cycads, Ginkgoales, Conifers, and Gnetales. These differ very much from one another, so much so that it is by no means impossible that the Gymnosperms are polyphyletic. The Cycads traced backwards show a maximum in the Jurassic, decreasing until about the end of the

Eocene they had shrunk to their present size. They begin about the Permian period, about which time the great class of the Pteridospermae, or seed-bearing ferns (the bulk of what used to be regarded as true ferns in the coal-measures, &c.), was disappearing, and show considerable relationship to the latter. Some of the fossil forms have actual \(\frac{1}{2} \) fis. with numerous sta., and it is quite possible that these are on the direct line of ascent to the Angiosperms. From what the Coniferae and Ginkgoales, which are first found about the beginning of the Permian, took their rise, is as yet quite uncertain, while we do not know enough about the Gnetaceae to draw many conclusions about them.

The fls. in most Cycads and Conifers take the form of cones, and whether each cone represents a fl. or an infl. has been much disputed. The sta. is of simple structure; in the Cycads there are several pollen-sacs, looking like the sporangia of Marattiaceae, on the lower side of a leaf-like organ; in the Conifers the sta. has usually fewer pollen-sacs and is more leaf-like, while in the Gnetaceae the anthers are sessile. The ovules are always naked in the sense of not being enclosed in an ovary formed of one or more hollow cpls., but they are usually protected in some way from the weather. Wind-pollination occurs.

In the Cycads a considerable mass of sporogenous tissue is formed in the ovule (mega-sporangium); one of the cells of this tissue gives rise to the embryo-sac (mega-spore). This behaviour is closely comparable to that of the higher Pteridophyta. In the embryo-sac the prothallus (endosperm) forms by cell-division, and archegonia in which the ova are contained develope at the micropylar end. The ovule is now mature and consists of an integument, nucellus, and embryo-sac and its contents.

In most Conifers the sporogenous tissue consists only of the cell which goes to form the embryo-sac. In the sac the same process goes

on as in Cycads.

In Ephedra the phenomena are very similar to those in Conifers; in Gnetum several embryo-sacs are frequently formed, and the division of the nucleus of the sac gives rise, not to a prothallus as in the cases above described, but to a number of free nuclei lying on the wall of the sac. Those in the upper part remain free, and one or more of them being fertilised, produce pro-embryos. The lower part of the sac becomes septate into multinuclear compartments (in some sp.), which become uninucleate cells of the primary endosp. as a result of nuclear fusion; in these sp. the primary endosp. is constituted before fert. In Welwitschia it is constituted in a similar way.

The whole question of the relationships of the G. is one of much difficulty. (See Angiospermae, Chalazogamae, Pteridophyta, Cycadaceae, Coniferae, Ginkgo, and refer also to Coulter and Chamberlain, Morphology of Gymnosperms, Campbell's Mosses and Ferns, Nawaschin in Mem. de l'Acad. des sc. de St-Petersbourg, XLII. 1894 (reviewed in Bot. Centr. 62, p. 324), and other papers referred to in the articles

quoted.)

Halopegia K. Schum. (Clinegyne p.p. BH.). Marant. 4 palaeotrop. Halopeplis Bunge. Chenopod. (A). 3 Medit., C. As.

Halophila Thou. Hydrocharid. 6 trop.

Halophyte, cf. Halo-.

Halophytum Spegazz. (Tetragonia p.p.). Chenopod (A). 1 Patag.

Halopyrum Stapf. Gramin. (10). I coast of Ind. Ocean.

Baloragidaceae (EP.; Halorageae of BH. incl. Callitrich., Hippurid.). Dicots. (Archichl. Myetiflorae; Rosales BH.; pp. xxxix, li). 7/1700 cosmop., esp. Austr. Land, marsh, or water herbs of various habits (cf. gen.), with great development of adv. r., opp, alt., or whorled usu. exstip. l., and inconspic. fls., sol. or in infl. Anatomy of interest. Fl. gor 3?, usu. bracteolate, reg., epig., usu. 4-merous. P4+4, or 4, or o; A4+4, obdipl., or fewer; G(I-4), multi-loc, usu. with I pend. anatr. ov. in each; styles free. Nut or drupe; embryo straight, in endosp. Related to Onagraceae, as reduced forms.

Classification and genera (Monogr. in Pfl. R., 1905):

Fr. not a schizocarp, ov .4—2-loc.; Loudonia (panicle), Haloragis (raceme, § , A 2-cyclic, usu. 4-merous), Meziella, Laurembergia (§ ?). Proserpinaca (3-merous). Fr. a schizocarp: Myriophyllum (ov. 4-2-loc.), Gunnera (ov. 1-loc.).

Haloragis Forst. Haloragid. 70 Austr., N.Z., Tasm., S.E. As.

Haloschoenus Nees = Rhynchospora Vahl p.p. (Cyper).

Halottachys C. A. Mey. Chenopod. (A). r E. Eur., W. As. P (3). Halotts Bunge = Halimocnemis C. A. Mey (Chenopod.).

Haloxylon Bunge. Chenopod. (B). 10 Medit., C. As. Steppe pl. of curious habit (fig. in Nat. Ph.); twigs jointed, apparently leafless.

Hamadyas Comm. ex Juss. Ranunc. (3). 4 Antarctic Am. Dioecious. Hamamelidaceae (EP; Hamamelidace of BH. incl. Myrothamn.). Dicots. (Archichl. Rosales; pp. xxiii, li). 18/50, chiefly subtrop. (N. and S.), with very discontinuous distr. areas. h, with usu. alt., simple or palmate stip. 1. Infl. racemose, often a spike or head, frequently with invol. of coloured br. Fl. § or § 9, often apet., rarely naked, hypoperi-, or epi-gynous, usu. without a disc. K 4—5, usu. 1mbr.; C 4—5, open or valv., pets. often long and rolled up like a watch spring in bud; A 4—5 or rarely fewer; G to G (2), usu. median, rarely obliquely placed, 2-loc. with term. divided style; ovules 1 or more in each loc., pend., anatr., with ventral or lat. raphe. Caps. loculicid. or septic.; exocarp woody, endocarp horny. Embryo straight, endosp. Some yield useful timbers, resins, &c.

Classification and chief genera (after Niedenzu); closely allied to

Cunoniaceae and thence to Saxifragaceae.

I. BUCKLANDIOIDEAE (ov. > 1 per loc.): (with C) Bucklandia, Rhodoleia; (without) Liquidambar, Altingia.

II. HAMAMELIDOIDEAE (ov. 1 per loc.): (sta. long, spikes) Parrotia, Fothergillia, Corylopsis; (sta. short; heads) Maingaya, Hamamelis, Sycopsis, Dicoryphe.

Hamamelis Gronov. ex L. Hamamelid. (II). 4 Chi., Jap., E.N. Am., incl. H. virginiana L. (N. Am., witch-hazel), cult. orn. shrub. It flowers in late autumn and ripens its fr. in the following year.

Indigenous, genuinely native.

Indigo, Indigofera; China green -, Rhamnus chlorophora Decne.;

Chinese -, Polygonum tinctorium Ait.

Indigofera L. Leguminosae (III. 6). 350 warm. 1. leptostachya DC., tinctoria L. and Anil L. furnish indigo. The plant is mown just before flowering, and soaked in water, whereby a yellowish solution is obtained. This on stirring and exposure to the air oxidises, and an insoluble precipitate of indigo is formed. The fls. are slightly explosive (cf. Genista).

Indokingia Hemsl. Araliaceae (1). 1 Seychelles.

Indomalaya, cf. Floral Regions, 11 (6) and (7).

Indovethia Boerlage. Ochnaceae (Violaceae BH.). I Borneo.

Induplicate (aestivation), leaf margins turned inwards; (vernation), Palmae.

Indusium, Filicales, Pteridophyta.

Inermis (Lat.), unarmed, thornless.

Inferae (BH.). The 1st series of Gamopetalae.

Inferior (ovary), enclosed in the receptacle.

Inflexed, bent inwards.

Inflorescence, the reproductive shoot, composed of, or bearing, a number of shoots of limited growth, termed flowers. Of two types, monopodial or racemose, where the first axis does not as a rule terminate in a fl., but grows steadily onwards; and sympodial or cymose, where the main axis soon terminates in a fl., and the growth is taken up by the lat. axes in succession. The typical raceme has an axis growing indefinitely up the middle, and successively younger fis on lat. branches, Cruciferae, Prunus, Ribes. There are also the cpd. raceme or panicle, the raceme with sessile fls. or spike, with its var. the catkin or pendulous spike, the corymb, or raceme with all the fl. stalks elongating to the same level, Iberis, the umbel, which may be imagined as a corymb with all the fls. springing from one point, Umbelliferae, the cpd. umbel, the head, which is a common receptacle with the fis. arranged in a dense mass with the youngest to the centre, Compositae, the cpd. head. The cyme may be mono. di- or pleiochasial, according as each branch bears upon itself 1, 2 or more branches; cf. dichasial cymes, &c. Many pl. possess mixed infls., with some branchings racemose, some cymose, Aesculus, Betulaceae, Labiatae, Verbascum.

Infundibuliform, funnel-shaped.

Inga Scop. Leguminosae (i. 1). 150 trop. and subtrop. Am., W.I. Ingenhouzia (Moc. et Sesse ex) DC. Malvaceae (4). 2 Mexico.

Ink berry (W.I.), Randia aculeata L.; - nut, Semecarpus Anacardium L. f., Terminalia.

Ipnum Phil. (Diplachne p.p. EP.). Gramineae (10). 1 temp. S. Am. Ipomoea L. (BH. incl. Aniseia, Batatas, Calonyction and Exogonium of Choisy, Mina Cerv., Operculina Silva Manso, Pharbitis Choisy, and Quamocht Moench.). Convolvulaceae (1. 4). 400 trop. and warm temp., chiefly climbing herbs or shrubs; many cult. orn. fls. (e.g. I. purpurea Roth, the morning glory). I. biloba Forst. is a char. creeping pl. of trop. beaches. I. Batatas Lam. (B. edulis Choisy) is the sweet potato, largely cultivated in warm countries for its tubers, which are used like potatoes. I. (Exogonium) Purga Hayne is the jalap; its rhizome gives off turnip-like roots about the size of apples. Wormeaten tubers are most valuable, as the non-resinous parts are eaten.

Ipomopsis Michx. = Gilia Ruiz et Pav. p.p. (Polemon.). Ipsea Lindl. (Pachystoma BH.). Orchidaceae (II. 9). 3 trop. Afr. and As.

Iré rubber, Funtumia elastica Stapf.

Iresine P. Br. Amarantaceae (3). 40 Am., Afr. Irnartea Ruiz et Pav. Palmae (1v. 1). 10 trop. Am. The stem is supported on aerial roots (cf. Pandanus). Some of the branches of these roots are thorny (cf. Acanthorhiza). In I. ventricosa Mart. (Paxiuba palm), the stem has a peculiar egg-like thickening about half-way up (cf. Bombacaceae, Jatropha).

Iriartella H. Wendl. (Iriartea p.p. EP.). Palmaceae (IV. 1). Amazon.

Iridaceae (EP., BH.). Monocotyledons (Liliiflorae; Epigynae BH.). 57 gen., 800 sp. trop. and temp.; the chief centres of distr. S. Afr. and trop. Am. Chiefly herbs with a sympodial tuber or rhizome below ground. L. usu. equitant in two ranks. Infl. term., cymose (1 fl. only in Crocoideae). Fl. &, reg. or ... P 3+3, petaloid, united below into a long or short tube; A 3 (the outer whorl), with extr. anthers; G (3), 3-loc., with axile plac. (rarely 1-loc. with parietal plac.); style usu. trifid and frequently ± petaloid. Ovules usu. ∞, anatr. Loculic. caps. Embryo small, in hard endosp.

Classification and chief genera (after Pax):

I. CROCOIDEAE (fl. solitary, or several developed centrifugally round a central one; plant small; l. not exactly in h phyllotaxy): Crocus, Romulea.

II. IRIDOIDEAE (fis. numerous, in spathes, several in each, usu. reg.; stem distinct; l. equitant): Iris, Moraea, Ti-

gridia, Sisyrinchium.

IXIOIDEAE (similar, but spathes 1-flowered; fl. often zygomorphic): Ixia, Tritonia, Gladiolus, Freesia.

Irideae (BH.) = Iridaceae.

Iris Tourn. ex L. Iridaceae (11). 200 N. temp. 2 in Brit., I. Pseudacorus L., the yellow flag, and I. foetidissima L, the gladdon. Many cult. orn. fl. Most have a sympodial rhiz. with equitant isobilat. 1., and small cymes of fls. in spathes. P petaloid, the sepals usu. bending downwards at the outer ends; opp. to them and almost resting on them are the petaloid styles, under which are the sta. with their extr. anthers. Just above the anther, on the outer side of the style, is a little flap, whose upper surface is the stigma. Bees entering the fl. to get the honey secreted by the ovary rub off their pollen upon the stigma; going farther in they get fresh pollen; and when they come out close the stigma flap, which prevents self-fert. (cf. Viola). The flat seeds are suited to wind-distr. [Dykes, The genus I., 1913.]

The dried rhiz. of I. florentina L. (Orris root) smells like violets,

and is used in perfumery; 'essence of violets' is made from it.

Irlbachia Mart. (Lissanthus BH.). Gentianaceae (1). 3 trop. S. Am. Irmischia Schlechtd. (Metastelma BH.). Asclepiad. (II. 1). 3 Mex.,

Iron bark, Eucalyptus; - shrub (W.I.), Sauvagesia erecta L.; - weed (Am.), Vernonia; - wood, Mesua, &c., applied to different woods in different countries.

Irregular (fl.), one in which any whorl has members not all alike.

Irritability, sensitiveness to stimuli.

A class of Pteridophyta. Only fam. Isoetaceae. Isoetes L. Isoetaceae. 50 temp. and trop. I. lacustris L. is the quill-wort of Brit. lakes, and I. echinospora Dur. is also found. Most are aquatics with short stout rhizomes and awl-shaped l., the habit being like that of Littorella, with which I. is frequently confused. The stem grows in thickness, but very slowly. The l. spread out at the base and sheath the stem. There are a number of roots, which branch dichotomously. Above the base of each l., on the inner side, is a large sporangium sunk in the tissue. The outer I have micro-, the inner mega-, sporangia, whilst the innermost 1. of all are usu. small and not sporangiferous. The sporangia are imperfectly chambered up by strands of tissue (trabeculae) running across them from front to back. The germination of the spores and the development of the embryo resemble the corresponding processes in Selaginella. I. is frequently placed with Eusporangiate Filicales (see Campbell, Mosses and Ferns). It differs so much from other Pteridophyta that determination of its relationships is of great difficulty. Juncaceae (EP., BH.). Monocots. (Liliiflorae; Calycinae BH.; pp. vii, liv). 8/300 in damp and cold places, temp., arct., trop. Mts. Usu. creeping sympodial rhiz., one joint of the sympodium appearing above ground each year as a leasy shoot. The stem does not often lengthen above ground, except to bear infl.; l. usu. narrow, sometimes centric. Infl. usu. a crowded mass of fls. in cymes of various types, usu monochas. Fl. usu. &, reg., wind-fert. P 3+3, usu. sepaloid, with odd l. of inner whorl post.; A 3+3 (or inner wanting), anthers dehisc. lat. or intr., pollen in tetrads; G (3), with axile or parietal plac. and ∞ or few anatr. ov.; style simple with 3 brush-like stigmas. Loculic. caps.; embryo straight, in starchy endosp. Chief Juncaginaceae = Scheuchzeriaceae. | genera: Prionium, Juncus, Luzula. Juncago Tourn. = Triglochin L.

Juncea Briq. = Bupleurum L. p.p. (Umbell.).

Juncella F. Muell. (7rithuria BH.). Centrolep. 2 S. Austr., Tasm. Juncellus C. B. Clark (Cyperus p.p. EP.). Cyper. (1). 10 warm.

Juncellus Griseb. = Cyperus L. p.p. (Cyper.). Junceus (Lat.), rush-like.

Juncoides (Dill.) Adans. = Luzula DC. (Junc.).

Juneus (Tourn.) L. Junc. 225 cosmop., chiefly in cold or wet places, rare in trop. 18 (rushes) in Brit. Usu. low herbaceous pl. with sympodial rhiz. giving off one leafy shoot each year. The l. are of various types, with large sheathing bases. Some are flat and grass-like, others needle-like, and still others centric in structure and standing erect. The infl. is a dense head or panicle, of cymose construction (usu. rhipidua or drepania). In some sp. it appears to be lat. on a leaf-like cylindrical stem, but is really only pushed to one side by the bract of the infl. Fl. protog. and wind-fert.

Rushes are largely used for making baskets, chair bottoms, &c. I. squarrosus L. is common on hill pastures in Brit.; it is eaten by sheep and forms a valuable part of their fodder when grass is scarce.

June-berry (Am.), Amelanchier.

Jungia L. f. Compositae (12). 15 S. Am.

Jungle, low or thin forest.

Juniper, Junipei us.

Juniperus Tourn. ex L. Coniferae (Pinac. 42; see C. for genus characters). 30 **. The juniper, J. communis L. (Asia and Eur. incl. Brit.), and J. Oxycedius L., &c. have needle l. throughout life; others, such as J. Sabina L., the savin (Eur. As.), have small l. closely appressed, as in Cupressus. Seedling forms of these are known (see Retinospora). The cone consists of 1—4 whorls of scales, one only being fertile, as a rule. In ripening the whole becomes a fleshy mass enclosing the hard seeds, and forming a good imitation of a true berry. The fruit is eaten by birds. That of J. communis is used in making gin. The wood of J. virginiana L. is the red cedar used for pencils; others also give useful timber.

Labdanum, Cistus creticus L., C. ladaniferus L.

Labellum, Canna, Marantaceae, Orchidaceae, Stylidiaceae, Zingiberaceae. Labiatae (EP., BH.). Dicotyledons (Sympet. Tubiflorae; Lamiales BH.). 200 gen. 3000 sp., cosmop.; chief centre the Medit. region. Some small groups are localised in their distribution, e.g. § II. in Austr. and Tasmania, III. in India, Malaya, China, &c., VIII. in Centr. Am., whereas the large ones, such as I. and IV., are cosmop. Most L. are land-plants, and herbs or undershrubs, smilar in habit and structure. Stem usu. square, with decussate simple exstip. 1., often hairy and with epidermal glands secreting volatile oils, which give char. scents to many. A few marsh-plants (Mentha, Lycopus, &c.), a few climbers (Stenogyne sp., Scutellaria. &c.), and a few small trees (Hyptis sp.). Many xero. with reduced, sometimes infolded, 1., hairiness, thick cuticles, &c., e.g. Rosmarinus.

The axis of the first order is not closed by a fl. but only those of later orders; thus the primary form of the infl. is racemose, and a simple raceme actually occurs in Scutellaria, &c. Usu. however a dichasial cyme, becoming cincinnal in its later branchings, occurs in the

axil of each l. upon the upper part of the main axis. In Teucrium, Nepeta sp., &c., the construction of this cyme is easily seen; but in most L. it is closely 'condensed' into the axil, so that all the fls. are sessile; but it is easily seen that the central fl. opens first and then those on either side of it (see diagram). The two condensed cymes at each node overlap the leafaxils and often form what looks like a whorl of fls.; this infl. is often called a verticillaster or false whorl.

Fl. & or gynodioec., ..., hypog., 5-merous with suppression in some

Floral diagram of Lamium album with indication of dich, double cincinnus at the sides (After Eichler.) The asterisk represents the missing posterior sta.

whorls. Usu. formula K(5), C(5), A4, G(2). K tubular, bell- or funnel-shaped, sometimes 2-lipped, persistent in fr.; C usu. 2-lipped with no clear indication of the individual petals; A 4, didynamous, or of nearly equal length, sometimes 2, epipet. with intr. anthers. G on a nectariferous disc (often developed on anterior side only), of (2) cpls. placed antero-post. Early in development a constriction appears in the ovary in the antero-post. line, dividing each cpl. into 2 loculi, so that the ovary becomes 4-loc. as it matures. Each of the 4 portions is nearly independent of the rest, and the style springs between them from the base of the ovary (i.e. is gynobasic); stigma 2-lobed. Placentae axile, each with I basal erect anatr. ovule with ventral raphe. Fr. usu. a group of 4 achenes or nutlets, each containing one seed; sometimes a drupe. Seed with no endosp. or very little; the radicle of the embryo points downwards (cf. Boraginaceae).

The fls. belong in general to classes H. and F. The 2-lipped C ensures that the visiting insect shall take a definite position in regard to the anthers and stigma whilst probing for the honey at the base of the fl. The lower lip acts as a flag to attract, and also as a landingplace, whilst the upper lip shelters the essential organs, which are usu. placed so as to touch the insect's back. The length of the C-tube varies very much, and with it the kind of visitors. Most Brit. sp. are bee fls., the long-tubed red fls. of Monarda &c. are butterfly fls., and a few sp. of Salvia &c. are humming-bird fls. The pollination-mech. is usu. simple; in Lamium, &c. the fl. is homogamous, the stigma merely projecting beyond the anthers so as to be touched first, but usu. the fl. is dichogamous (protandr.), often with movements of the essential organs, e.g. in Teucrium, &c. The levermechanism of Salvia is almost unique. Thymus, Origanum, and their allies, have nearly regular fis. visited by a more miscellaneous selection of insects. In many L., esp. § VI., interesting distrs. of sex appear, esp. gynodioecism.

A few disperse their fr. by aid of the persistent bladdery K, or by hooks formed from the K teeth. The stalks are often hygroscopic and move in such a way as to favour dispersal in wet weather.

Useful on account of their volatile oils; many, e.g. Thymus, Ocimum, Origanum, Salvia, &c., used as condiments. Oils and perfumes are obtained by distillation from Rosmarinus, Pogostemon, Lavandula, &c. Food products from Stachys sp.

Classification and chief genera (after Briquet, from whose account much of the above is condensed); closely allied to Verbenaceae; from Boraginaceae the position of the radicle sharply separates them, whilst the similarity to Scrophulariaceae, &c. is largely in minor chars.

Style not gynobasic. Nutlets with lateral-ventral attachment and usu. large surface of contact (often > \frac{1}{2} as high as ovary).

AIUGOIDEAE (seed exalb.);

1. Ajugeae (corolla various; upper lip if present rarely concave; sta. 4 or 2; anther 2-loc.; nutlets = wrinkled): Ajuga, Teucrium.

Rosmarineae (corolla strongly 2-lipped; upper lip very concave and arched; sta. 2; anthers 1-loc.; nutlets smooth): Rosmarinus (only genus).

II. PROSTANTHEROIDEAE (seed albuminous): Prostan-

thera.

B. Style perfectly gynobasic. Nutlets with basal attachment and usu. small surface of contact, rarely with ± basal-dorsal attachment.

III. PRASIOIDEAE (nutlet drupaceous with fleshy or very thick exocarp and hard endocarp): Stenogyne, Gomphostemma.

IV. SCUTELLARIOIDEAE (nutlet dry; seed ± transversal; embryo with curved radicle lying on one cot.): Scutellaria.

LAVANDULOIDEAE (nutlet dry; seed erect; embryo with short straight superior radicle; disc-lobes opp. to ovary-lobes; nutlets with # distinct dorsal-basal attachment; sta. 4 included; anthers 1-loc. at tip through union of thecae): Lavandula (only genus).

VI. STACHYDOIDEAE (ditto, but disc-lobes, when distinct. alt. with ovary-lobes; nut with small basal attachment; sta. ascending or spreading and projecting straight forwards): Marrubium, Nepeta, Dracocephalum, Prunella, Phlomis, Galeopsis, Lamium, Ballota, Stachys, Salvia, Monarda, Ziziphora, Horminum, Calamintha, Satureia, Origanum, Thymus, Mentha, Pogostemon.

OCIMOIDEAE (as VI., but sta. descending, lying upon VII.

under lip or enclosed by it): Hyptis, Ocimum.

VIII. CATOPHERIOIDEAE (nutlet dry; seed erect; embryo with curved radicle lying against the cotyledons): Catopheria.

Labiate (C), with projecting lip.

Lateral branching, cf. Branch.

Latex, a milky fluid contained in special vessels or cells of the tissues, Alismaceae, Apocynaceae, Araceae, Asclepiadaceae, Euphorbiaceae, Compositae (Cichorieae), Galactia, Moraceae, Sapotaceae, &c. Cf. Guttapercha, Rubber, Balata; laticiferous, latex-bearing.

Lathraea L. Orobanchaceae. 5 temp. Eur., As. L. Squamaria L. in Brit. (tooth-wort) is a total parasite living upon the roots of hazel, beech. &c. It has a thick rhiz. bearing 4 rows of tooth-like scaly 1. The fl. shoot comes above ground and hears a raceme of purplish fls., all bent round to the same side of the infl., protogynous. The scales upon the rhiz, are hollowed, each containing a branched cavity opening to the outside by a narrow slit at the base of the back of the l. This arises by a development similar to that which forms the chambers in the l. of Empetrum, Cassiope, &c. In the small lat. cavities opening out of the main one there are found peculiar glandular organs, resembling those of insectivorous plants. Small insects, &c. are often found in these leaves (cf. bladders of Utricularia, &c.) and it has been supposed that these organs absorb their proteids like the glands of Drosera, &c. This however is doubtful. L. Clandestina L. is parasitic upon willows. The capsule of L. splits explosively. [For details see Heinricher, Die Schuppenwurz, Stuttgart, 1908.]

Lathriogyna Eckl. et Zeyh. Leguminosae (III. 3). I S. Afr. Lathrophytum Eichl. Balanophoraceae. 1 Rio de Janeiro.

Lathyrus (Tourn.). L. (incl. Orobus L.). Leguminosae (111. 9). 110 N. temp., and Mts. of trop. Afr. and S. Am. 10 in Brit. (pea), including L. Aphaca L. and L. Nissolia L. The former has large green stipules performing assim. functions, whilst the l. is transformed into a tendril; the latter has its petioles flattened into phyllodes and has no I. blade at all (see Acacia). L. macrorrhisus Wimm. has tuberous roots which may be eaten like potatoes. L. sativus L. (Jarosse) and L. Cicera L. are cult. in S. Eur. as fodder and are also eaten like chick-pea (Cicer). L. odoratus L. is the sweet-pea. The fl. is like that of Vicia; on the style is a tuft of hairs that brushes the pollen out of the apex of the keel, where it is shed by the anthors. L. latifolius (everlasting pea) also cult. orn. fl.

Lati- (Lat. pref.), broad; -folius, broad-leaved, &c. &c. Latipes Kunth. Gramineae (3). I Seneral to Sind.

Lead-tree (W.I.), Leucaena glauca Benth.; -wort (W.I.), Plumbago. Leaf, a thin green expanded organ, borne on the stem at the nodes. The interior of an ordinary l. is made up of a mass of spongy green tissue (mesophyll), covered by an epidermis which contains stomata leading to the intercellular spaces in the interior, and whose outer wall is covered by a cuticle of waxy or corky nature. The vascular bundles that run through the l. and hold it outstretched are called the veins or nerves. The l. shows distinction into a base abutting on the stem and often bearing a pair of green or membranous expansions (stipules), and a blade or lamina, often with a stalk or petiole between. Such a 1. has an upper or ventral surface, and a lower or dorsal, and is markedly dorsiventral in structure; it places itself \pm horiz. in what is called its fixed light position. Others (isobilateral, q.v.) have symmetrical structure on both sides, and place themselves with their edges to the light (phyllodes (q.v.) also come into this category), and yet others (centric, q.v.) have symmetrical structure all round, and stand with their apices to the light. Many l. exhibit sleep movements

at night, or movements during heat or dryness (cf. Movements). The fall of a l. is often effected by an absciss-layer, or stratum of cork which separates it from the stem, and then splits, leaving a leaf-scar upon the stem. L. with such a layer are called articulate, without, non-articulate.

Under other than mesophytic conditions such structure as just described shows many modifications; cf. Climbing Plants, Insectivorous Plants, Parasites, Saprophytes, Water Plants, Xerophytes. It is also modified for Storage (q.v.) of reserves, or for Vegetative

Reproduction (q.v.).

In external form 1. show very great variety, and the grouping of gen. into sp. is largely determined by this, so that it is necessary to understand the use of the technical terms employed in such work, before one can use a flora with any advantage. An outline of such terms and their use follows.

Descriptive Terms. The student should practise describing leafy shoots until expert in handling terminology, but there is no need to commit the terms to memory. At first he should describe in detail in the order given below, but afterwards try to render his descriptions short and pithy without sacrifice of essentials; this can only be well done by comparison with related forms to see what points are common to all.

L. as to phyllotaxy (q.v.) or arrangement may be radical, or on the subaerial stem (cauline); whorled (verticillate), opposite (and then decussate if each pair is 1 the next, connate if the two are concrescent as in Lonicera, anisophyllous if unequal in size or shape), or alternate (the phyllotaxy fraction may be given, or the number of ranks described by the terms di-, tri-stichous, &c.). With regard to insertion or mode of union with the stem the l. may be petiolate or sessile (i.e. with or without stalk respectively; the petiole is descr. like a stem), auricled (with two lobes of the blade overlapping the stem), amplexicaul (the lobes clasping the stem), sheathing (as in Grasses, the leaf-base forming a tube round the stem), perfoliate (the leaf united round the stem, as in Bupleurum), decurrent (continued by a wing on the stem, as in thistles), &c. It may bear a liquie or scale at the upper end of the leaf-base or sheath, as in Grasses. It may be stipulate or exstipulate (with or without stip. respectively); the shape, &c. of the stip. is described as if they were 1. and they may be free or adnate (F in fig., concrescent with the leaf-base or petiole, as in rose), united to other stip., inter- or intra-petiolar, branched, &c. (see Rubiaceae), ochreate (sheathing, as in Polygonaceae), or modified in various ways. The venation (arrangement of the veins) may be pinnate or palmate; in the former case there is a midrib with lat. veins branching from it, in the latter several equal veins spread out in the l. like the ribs of a fan, from one point. The further ramification of the veins is descr. by net-veined (irreg. meshwork, as in most Dicots.), parallel-veined (meshes more or less rectangular, as in most Monocots.), fork-veined (veins forking into two. as in Ferns).

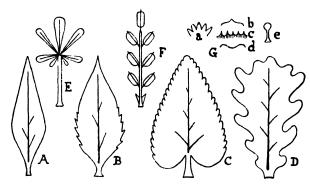

L. are divided into simple and compound, as the stalk bears one or several separate leaflets. In the latter case the leaflet is desc. as if

it were a l., and the common stalk is called the rachis. If the leaflets spring from the sides of the rachis, as in the pea, the l. is pinnate (F), if all from one point palmate (E). If the leaflets of a pinnate l., as in many Acacias, are again pinnately cpd., the l. is bipinnate. Al. with 3 leaflets (as in clover) is ternate or tri-foliolate, with 3 ternate leaflets biternate. Pinnate l. may be equally (pari-) pinnate (with an even number of leaflets), unequally (impari-) pinnate (with an odd leaflet at the end), or interruptedly pinnate (large and small leaflets alt. as in many Rosaceae). A palmate l. with 5 or 7 leaflets is often called digitate. The leaflet may have stipule-like organs, or stipels (adjective stipellate).

The leaf may be dorsiventral, isobilateral, or centric, or replaced

by a phyllode, scale, pitcher, or other organ.

The shape of the leaf-blade or leaflet itself, if simple, or the outline of a cpd. 1., may be needle-shaped or acicular as in Pinus, subulate or awl-shaped, tubular as in onion, linear (long and narrow as in Grasses), lanceolate (about 3 times as long as broad, tapering gradually towards the tip; A in fig.), ovate (about twice as long as broad, and tapering towards the tip; B), cordate (similar, but heart-shaped at the base; C), elliptical (tapering equally to base and tip, and somewhat narrow), oval (do. but wider), oblong (sides) for some distance, the ends tapering rapidly; F), reniform (kidney-shaped), orbicular (circular in outline; if the petiole is inserted at the middle of the blade, as in Tropaeolum, this leaf is termed peltate), hastate (with two pointed

FORMS OF LEAVES. A, subsessile, exstip., lanceolate with cuncate base, entire, acute. B, sessile, exstip., ovate, serrate below, entire above, acum. C, petiolate, exstip., cordate, crenate, obtuse. D, sessile, exstip., somewhat obovate, pinnatifid sinuate, obtuse. E, petiolate, exstip., palmate (digitate), with obtuse oblanceolate leaflets. F, impari-pinnate with triangular adnate stips.; leaflets shortly stalked, oblong, apiculate, the laterals oblique. G, a, plicate l. in section, b, mucronate apex, c, dentate spiny margin, d, retuse apex, c, glandular hair.

lobes sticking out horiz at the base), sagittate (two lobes projecting towards the stem), spatulate (spoon-shaped, as in daisy), &c. If a l. be of lanceolate shape but the general tapering be towards the base, it is called oblanceolate (E); so also obovate or obcordate. If wedgeshaped, tapering to the base, it is cuneate. The l. may be oblique or asymmetrical (P), when the midib divides it into unequal halves, as

in Begonia.

The 1. (or leaflet) may be entire, i.e. without notches in the margin (A), or incised; the margin may also be fringed or fimbriate. cartilaginous, membranous, wavy or undulate (as in holly), curled or crisped (as in sea-kale), spiny (Gc), glandular (with sticky hairs or glands; Ge), ciliate (with fine projecting hairs), &c. If the margin has small teeth pointing forwards, it is serrate (B), if pointing outwards, dentate (Gc); if the teeth are rounded but the notches sharp, the margin is crenate (C), if both teeth and notches are rounded, it is sinuate (D). If the depth of the divisions is equal to \(\frac{1}{2}\) the distance from midrib to margin, i.e. if the incisions are conspicuous in proportion to the size of the blade, other terms come into use. notching is from \(\frac{1}{2}\) to \(\frac{1}{2}\) the depth, the l. is -fid (D), if \(\frac{1}{2}\) to \(\frac{2}{2}\), -partite, if over \(\frac{3}{4}\), -sect. Prefixes of pinnati- or palmati- are used before these terms to express the particular form of notching, which depends upon the venation. The portions into which the l. is thus divided are termed lobes or segments. Special terms are employed for such l. as mustard (lyrate, the end lobe very large), dandelion (runcinate, the lobes pointing backwards), hellebore (pedate), &c.

The apex may be acute (pointed; A), obtuse (blunt; C), acuminate (tapering in hollow curves to a long fine point; B), emarginate (noteched), retuse (broadly do.; Gd), mucronate (with large stiff point on nearly straight edge; Gb), apiculate (do. with small point; F), truncate or praemorse (broad, straight end, as if bitten off), cirrhoss (tendrilled).

The surface of the l., as of other parts, may be glabrous (without hairs), pilose (soft, scattered hairs), downy or pubescent (fine, soft hairs), hairy (coarser), hispid (rough, bristly), tomenlose (with a cottony felt), woolly, glandular-hairy; scabrous (rough), smooth, prickly, glaucous (with bluish waxy gloss), reticulate (netted), rugose (ridged or wrinkled), squarrose (roughly scurfy), &c. Hairs may be spreading or appressed (flattened down), simple (unbranched), glandular (Ge), bifid, stellate (like a starfish), squamate (scaly), &c.; prickles may be straight or curved, bent backwards (retrorse), &c. The l. may be dotted with oil-glands, or variegated in colour, green, red, &c.; frequent shades are fulvous (tawny), rubiginose (rust-coloured), &c. The texture may be thin or herbaceous, coriaceous (leathery), succulent or fleshy, membranous or scarious (thin, dry, not green, and flexible or stiff respectively), &c.

L. may be evergreen or deciduous (falling in winter); in this case articulate (cut off by special absciss layer and falling early), or non-articulate (hanging on to the stem, though dead, for an indefinite period, as in beech hedges, oak, &c.). The vernation, or folding in bud, is descr. like the aestivation of flower-buds (q.v.); the following terms are also used to describe the folding of the individual 1, conduplicate (folded lengthwise as in oak), pluate (folded several times;

Ga), involute (margins rolled inwards), revolute (outwards), reclinate (apex bent down to base), convolute (rolled spirally, as in Musa); conduplicate l. overlapping younger ones thus <<>>, as in Iris, are called equilant.

When a character is not accurately described by one of the terms given, but is rather half-way between two, both are used; thus a l. may be linear-lanceolate or ovate-cordate. Sub-, meaning 'nearly,' is often used as a prefix to adjectives, e.g. subsessile, subacute. As an example of the use of these technical terms, we quote from Lindley the descriptions of two leaves:

Lilac: leaves opposite, exstipulate, roundish-cordate, very acute,

thin, smooth, rather longer than the linear channelled petiole.

Garden Strawberry: leaves all radical, ternate, dark-green, somewhat shining, very coarsely serrated; with strong parallel oblique veins, silky beneath; leaflets nearly sessile, roundish oblong, entire towards the base, shorter than the semi-cylindrical hairy petioles; stipules membranous, lanceolate, acuminate, half adnate.

For other details of leaf structure and modification, see Anisophylly, Bud, Climbing Plants, Concrescence, Dimorphism, Driptip, Insectivorous Plants, Parasites, Phyllodes, Phyllotaxy, Saprophytes, Stipule, Storage, Vegetative Reproduction, Water-plants, Xerophytes, and

Leguminosae (EP., BH.). Dicots. (Archichl. Rosales; pp. xxiii, li). The third largest fam. of flg. pl., with 600/12000, cosmop. Mimosoideae and Caesalpinioideae are mostly trop., Papilionatae largely temp. (abundant on steppes, &c.). (Cf. Taubert in Nat. Pf.)

Living in every soil and climate they show great variety in habit—trees, shrubs, herbs, water-plants, xerophytes, climbers, &c. The roots of most exhibit peculiar tubercles—metamorphosed lat. roots containing peculiar bacterial organisms (Rhizobium sp.). Plants provided with these are able to take up much more atmospheric nitrogen. The plant appears actually to consume the 'bacteroids' which live in its cells, after they have stored up in themselves a considerable amount of nitrogenous material. Hence the value of the L. as a crop on poor soil, or as preceding wheat in the rotation of crops; for instead of impoverishing the soil they enrich it, either by the nitrogen contained in their roots and liberated as these decay, or by that of the whole pl. if ploughed in as 'green manure.'

Stem commonly erect; many climbers. Some, e.g. Vicia, climb by leaf-tendrils, some, e.g. Bauhinia, by stem-tendrils, some by hooks (modified in Caesalpinia, &c., emergences in Acacia, &c.), some by twining. Creeping stems, rooting at the nodes, also occur. Thorns, usu. modified branches (e.g. Gleditschia) or stipules (Acacia), are common. The stems of the erect trop. sp. often branch so that the branches run parallel and erect, and bear crowns of 1. at the top. The stems of many lianes are peculiarly shaped, often flat, or corrugated

in various ways, owing to peculiar growth in thickness.

L. usually alt., stip., and nearly always cpd. Many have very small l., e.g. Ulex, or scaly l. and flat stems, e.g. Carmichaelia. The stipules vary much in size, &c. (see Acacia, Lathyrus, Vicia). The l. usu. perform sleep-movements at night, some moving upwards, some downwards, or in other ways, but finally usu. placing the leaflet edgewise to the sky. In Mimosa and Neptunia the l. are sensitive to a touch and at once assume the sleep-position, recovering after a time. In Desmodium gyrans the lat. leaflets execute continuous spontaneous movements as long as the temperature is high enough.

Infl. apparently always racemose, but with variety; simple raceme very common, also panicle and spike. Dorsiventral racemes, resembling the cymes of Boraginaceae, also occur (e.g. Dalbergia). The fls. are regular (and then frequently polygamous) or irreg. (and then usu. y); recept. usu. convex or flat, so that at most the fl. is slightly perig. K developed in ascending order, usu. 5-merous, the odd (oldest) sepal anterior; the sepals \(\pmu\) united. C polypetalous, alt. with the K; aestivation valvate (Mimosoideae), ascending imbr. (Caesalpinioideae).

Floral diagrams of Vicia Faba (Papilionatae) and Acacia latifolia (Mimosoideae), after Eichler (modified).

or descending (Papilionatae). In many cases it is 1 to a high degree, having a large petal posterior (vexillum or standard), two lateral (alae or wings), and two anterior \pm joined to form a keel or carina. A typically of 10 sta., free or united into a tube; in the latter case the tenth sta. (the posterior one) often remains free, so as to leave a slit in the tube, only covered loosely by this sta. Many variations are found. In cases where a keel is present, the sta. are enclosed in it. $\underline{\underline{C}}$ typically of one cpl. with its ventral side directly posterior; long style and terminal stigma. There are two rows of ovules (alt. with one another so as to stand in one vertical rank), anatr. or

amphitr., ascending or pend.

Fertilisation (Papilionatae). The keel encloses the essential organs. protecting them from rain, &c. and rendering the fl. complex. Honey is secreted by the inner sides of the sta. near their base, and accumulates in the stamen-tube round the base of the ovary. The tenth sta, is free of the tube, and at the base, on either side of it, are two openings leading to the honey. The honey is thus concealed and at some depth, so that a clever insect with a tongue of moderate length is required. All this points to the P. being bee-flowers (class H), as in fact is the case. Insects alight upon the wings and depress them by their weight, whilst they probe for honey under the standard. The wings are always joined to the keel, usually by a protuberance in the former fitting into a suitable hollow in the latter, so that the keel is thus depressed likewise. This causes the emergence of the essential organs, the stigma usu. coming first, so that a fair chance of crossfert, exists. Self-pollination usu, occurs when the insect flies off,

leaving the keel to return to its former position.

"Four different types of structure may be distinguished (in Papilionatae) according to the manner in which the pollen is applied to the bee: (1) P. in which the sta. and stigma emerge from the carina and again return within it. They admit repeated visits; e.g. Trifolium, Onobrychis. (2) P. whose essential organs are confined under tension and explode. In these only one insect's visit is effective; e.g. Medicago, Genista, Ulex. (3) P. with a piston mechanism which squeezes the pollen in small quantities out of the apex of the carina, and not only permits but requires numerous insect visits; e.g. Lotus, Ononis, Lupinus. (4) P. with a brush of hairs upon the style which sweeps the pollen in small portions out of the apex of the carina. They for the most part require repeated insect visits; e.g. Lathyrus, Vicia." (Muller.) Cleistogamy is fairly common. several cases the stigma in the unvisited fl. lies in the keel among the pollen, but it has been shown that it only becomes receptive (if young) when rubbed, so that autogamy does not necessarily occur. For the phenomenon of enantiostyly (right- and left-styled fls.) see Cassia. Some have fis. which after fertilisation bury themselves in the earth and there ripen their fruit; e.g. Arachis, Lathyrus, Trifolium, Vicia, Voandzeia, &c.

Fr. typically a *legume*, or pod opening by both sutures. In some the pod is constricted between the seeds, forming a *lomentum* which breaks up into indeh. one-seeded portions. The pods frequently open explosively, the valves twisting up spirally, e.g. in Ulex, Cytisus sp.,

&c. In Colutea, &c. they are inflated. Some are eaten by animals, but the seed-coats are hard enough to preserve the seeds from injury. Some have a coloured fleshy aril (Acacia sp., &c.). Still others have hooked pods, e.g. Medicago, Mimosa. The seed is exalb.; usu. large store of reserves in the cot.

Economically the L. are most important. The seeds of many sp. form important food-stuffs, e.g. of Arachis (see Edible Products for common names), Cajanus, Cicer, Dolichos, Glycine, Lathyrus, Lens, Lotus, Lupinus, Phaseolus, Pisum, Vicia, Voandzeia, &c. The pods of Ceratonia, Tamarindus, Phaseolus, Prosopis, &c. are also eaten. A great number are valuable as fodder, and known as artificial grasses, e.g. Trifolium, Medicago, Onobrychis, Lotus, Vicia, &c. Many trop. and subtrop. sp. yield valuable timber, e.g. Acacia, Albizzia, Dalbergia, Gleditschia, Hymenaea, Melanoxylon, Pericopsis, Pterocarpus, Robinia, Sophora, &c.; Crotalaria and others are sources of fibre; Acacia, Genista, Haematoxylon, Indigofera, &c. yield dyes; gums and resins are obtained from Acacia, Astragalus, Copaifera, Hymenaea, &c.; oil is expressed from the seeds of Arachis and Voandzeia; kino is obtained from Pterocarpus, and so on. See Fconomic Products and genera.

Classification and chief genera (after Taubert): nearly related to Rosaceae (espec. Chrysobalanoideae) and Connaraceae. Sometimes

made a separate order, with the 3 divisions as fams.

The primary division is:

I. MIMOSOIDEAE. Fls. reg., C valvate.

II. CAESALPINIOIDEAE. Zygomorphic; corolla-aestivation imbricate-ascending.

III. PAPILIONATAE. Zygomorphic papilionaceous; corollaaestivation imbricate-descending.

These are again subdivided as follows:

I. MIMOSOIDEAE.

A. Calyx valvate.

a. Sta. more than 10.

 Ingeae (A united): Inga (l. once pinnate, G 1), Calliandra, Pithecolobium, Albizzia (l. twice pinnate, G 1, pod flat straight, not elastic).

2. Acacieae (A free): Acacia (only genus).

Sta. as many or twice as many as pets. [flat).
 Euminoseae (anther glandless): Mimosa (pod compressed.

4. Adenanthereae (anther in bud crowned by a gland; endosperm): Neptunia (head of fl. 3 or neuter below), Prosopis.

5. Piptadenieae (do., no endosp.): Piptadenia, Entada.

B. Calyx imbricate.

6. Parkieae: Parkia (fls. in heads), Pentaclethra (spikes).

II. CAESALPINIOIDEAE.

A. Calyx in bud quite undivided or tubular below.

a. L. simple or one pair of leaflets. A 10 or less.

4. Bauhinieae: Cercis (fl. papilionate), Bauhinia (not so, 1. of two equal lobes or parts).

b. L. once pinnate (exceptions). A ∞ or rarely 9—13.

Swartziege (Toungtege): Swartzia (A . C I or o).

c. L. bipinnate, or once pinnate and then sta. 5.

1. Dimorphandreae: Dimorphandra (sta. 5 with 5 stds.).

Calyx in bud quite or very nearly polysepalous.

2 anterior pets. modified to large glands, anthers opening by 6. Kramerieae: Krameria (only genus).

2 anterior pets. developed or not, but not glandular. L. some or all bipinnate.

- Eucaesalpinieae: Gleditschia, Haematoxylon, Poinciana, L. once pinnate. | Caesalpinia.
- Cassieae (anthers basifixed, opening by term. pores): Cassia (no disc, C 5, l. paripinnate), Ceratonia (marked disc).
- Amhersticae (dorsifixed, no pores; ovary adnate behind to torus): Hymenaea, Tamarındus, Vouapa, Amherstia.
- Sclerolobieae (ovary free, ovules > 3): Sclerolobium.
- Cynometreae (ovules 1 or 2): Copaiba (Co, K4, G stalked).

III. PAPILIONATAE.

Sta. free. Sophoreae (l. pinnate): Myroxylon, Ormosia, Sophora,

Podalyricae (simple or palmate): Anagyris, Baptisia, Po-Sta. mon- or di-adelphous. [dalyria, Daviesia, Pultenaea.

Lomentum.

Hedysareae: Coronilla, Hedysarum, Onobrychis, Aeschynomene, Patagonium, Arachis, Zornia, Desmodium.

Legume or indeh. pod.

L. absent. Eremosparton (6, Galegeae). L. present.

I. L. or leaflet without stipels.

(1) L. simple or palmate.

Lf. with 3 entire leaflets. 3. Genisteae (shrubs): Bossiaea, Rafnia, Lotononis, Aspalathus, Crotalaria, Lupinus, Genista, Laburnum, Ulex, Cytisus.

6. Galegeae (herbs): Indigofera, Psoralea, Tephrosia, Robinia, Sesbania, Swainsona, Colutea, Astragalus, Oxytropis (cf. ** L. with 5 entire leaslets.

(below). Loteae: Anthyllis (pod indeh. or late dehisc.), Lotus.

5. Loteae: Annay.... (1981). Mei (A (9) + 1, C persistent). Trifolieae: Ononis (A (10)), Medicago, Melilotus, Trifolium

L. pinnate.

Leasstalk ending in bristle or tendril.

Vicieae: Cicer, Vicia, Lens, Lathyrus, Pisum, Abrus.

+ Pod dehisc. in two valves.

§ Sta. filamentous.

Phaseoleae (ovary surrounded by disc): Clitoria, Glycine, Kennedya, Erythrina, Apios, Butea, Mucuna, Galactia, Canavalia, Rhynchosia, Eriosema, Phaseolus, Voandzeia,

Galegeae (no disc): as above. [Vigna, Dolichos.

§§ Some or all sta. broadened at apex.

Loteas: as above. # Pod indeh.

8. Dalbergieae: Dalbergia, Pterocarpus.
II. Leaves or leastest with stipets.
10. Phaseoleae: (pod dehiscent) as before.
8. Dalbergieae: (pod indehiscent) as before.

Compositae (6). I California. Lemmonia A. Gray. Hydrophyllaceae. 1 California. Lemna L. Lemnaceae. 6 cosmop.; 4 in Brit. (duckweed). The plant consists in most, e.g. L. minor L., of a flat green floating blade. the stem, which performs leaf-functions. From the under side hangs down a long adv. root, with well-marked root-cap, visible to the eye. No l. The stems are oval and slightly turned up at the ends, so that if two are placed near together in water, they will run against one another and adhere by the tips. In the post, portion on either side is a groove under the edge. In this arise branches which may either (as in L. trisulca L., &c.) remain in union with the parent shoot, or become detached and give rise to new plants. In autumn a number

of these are formed ready to start growth next spring, whilst the mother pl. sink to the bottom. Fls. also borne in these grooves; spathe very

reduced, with 2 & fls. (each 1 sta.) and a ? (1 cpl.).

Lemnaceae (EP., BH.). Monocots. (Spathiflorae; Nudiflorae BH.; pp. v, liv). 4/18, free-swimming perenn. water pl. with no l. (cf. description of Lemna). Fl. unisexual, monoec., naked; & of I sta., of 1 cpl, with 1-6 basal, erect, orthorr, to anatr. ov. Endosp. slight. Often regarded as very reduced Araceae. Chief genera: Spirodela (shoots with several r.), Lemna (with 1 r.), Wolffia (no r.). Lemnopsis Zipp. Podostem. (inc. sed.). 5 Malaya.

Lilac, Syringa vulgaris L.; Californian -, Ceanothus; Indian -, Melia Lagerstroemia; West Indian -, Melia.

Lilaea Humb. et Bonpl. Scheuchzeriaceae (Naiad. BH.). I Rockies,

Liliaceae (EP., BH.). Monocots. (Liliistorae; Coronarieae BH.). One of the largest fams. of slowering plants; 250 gen., 3700 sp., cosmop.; the smaller groups often confined to definite storal regions. Most are herbs with sympodial rhiz. or bulbs; a few trop. and warm temp. forms, e.g. Yucca, Dracaena, &c., are shrubs or trees, often with an unusual mode of growth in thickness. Many are xero.; some, e.g. Aloe and Gasteria, are succulent; others, e.g. Phormium, have hard isobil. 1; others, e.g. Dasylirion, have tuberous stems and narrow 1.; Bowiea only produces leafy shoots in the wet season. Smilax, Gloriosa, &c., are climbing pl., the former with peculiar stipular tendrils. Ruscus exhibits phylloclades.

Infl. most commonly racemose; fls. with no bracteoles; when the latter occur, the further branching from their axils usually takes a

cymose form, especially that of a bostryx, as in Hemerocallis. The apparent umbels or heads of Allium, Agapanthus, &c. are really cymose. Sol. term. fls. occur in tulip, &c. Fls. usu. 4, reg., pentacyclic, 3-merous (rarely 2, 4, or 5), hypog. P 3+3, free or united, petaloid or sometimes sepaloid; A 3+3 or fewer, rarely more, usu-

ally with introrse anthers; G (3) usu. sup., rarely inf. or semi-inf., 3-loc. with axile, or rarely 1-loc. with parietal plac.; ovules usu. . in two rows in each loc., anatr. Fr. usu. capsular, loculic. or septic., sometimes a berry. Seed with straight or curved embryo, in abundant fleshy or cartilaginous, never floury, endosp.

Fls. usu. insect-pollinated. Honey in Scilla, Allium, &c., is secreted by glands in the ovary-wall between the cpls.; in other cases by glands on the bases of the perianth-l. (see Müller's Fert. of Fls.). Yucca (q.v.) has a

unique pollination-method.

Economically the L. are of no great value. The chief food plants are Allium and Asparagus; Phormium, Yucca,

Diagram of Convallaria (after Eichler).

and Sansevieria yield useful fibre; Smilax, Urginea, Aloe, Colchioum, Veratrum, &c., are medicinal. Xanthorrhoea and Dracaena yield resins; Chlorogalum is used as soap. Many are favourite garden and greenhouse plants, e.g. Convallaria, Tulipa, Fritillaria, Lilium, Agapanthus, Kniphofia, Funkia, Hyacinthus, Gloriosa, and many more.

Classification and chief genera (after Engler): the L. are closely allied to Juncaceae; usu. they can be distinguished by their petaloid P. but many L. have a sepaloid P, e.g. Xanthorrhoca, Kingia, &c., and in these cases almost the only distinction is the absence in L. of the long thread-like twisted stigmas of J. BH. unite these genera, and some others, to Juncaceae, and place sub-fams. VIII and IX in Haemodoraceae. Warming splits up the family into Colchicaceae, Liliaceae, and Convallariaceae.

I. MELANTHIOIDEAE (rhiz., or bulb covered with scale-1. and with term. infl.; anthers extr. or intr.; caps. loculic. or septic.; fr. never a berry): Tofieldia, Narthecium, Veratrum, Gloriosa, Colchicum.

II. HERRERIOIDEAE (tuber, with climbing stem; 1. in tufts; small-flowered racemes at base of these or in panicles at ends

of twigs; septic. caps.): Herreria (only genus).

III. ASPHODELOIDEAE (rhiz. with radical l., rarely stem with crown of 1. or leafy branched stem or bulb; infl. usu. term., a simple or cpd. raceme or spike; P or (P); anthers intr.; caps., rarely berry): Asphodelus, Chlorogalum, Bowiea, Funkia, Hemerocallis, Phormium, Kniphofia, Aloe, Gasteria, Haworthia, Aphyllanthes. Lomandra, Xanthorrhoea, Kingia.

LIME 385

ALLIOIDEAE (bulb or short rhiz.; cymose umbel ± enclosed by two broad or rarely narrow l., sometimes joined; infl. rarely of 1 fl.): Agapanthus, Gagea, Allium, Brodiaea.

V. LILIOIDEAE (bulb; infl. term., racemose; P or (P); anthers intr.; caps. loculic., except in Calochortus): Lilium, Fritillaria,

Tulipa, Scilla, Ornithogalum, Hyacinthus, Muscari.

VI. DRACAENOIDEAE (stem erect with leasy crown, except in Astelia; 1. sometimes leathery, never fleshy; P free or united at base; anthers intr.; berry or caps): Yucca, Dasylirion, Dracaena. VII. ASPARAGOIDEAE (rhiz. subterranean, sympodial;

berry): Asparagus, Ruscus, Polygonatum, Convallaria, Trillium.

VIII. OPHIOPOGONOIDEAE (short rhiz., sometimes with suckers, with narrow or lanceolate radical I.; P or (P); anthers intr. or semi-intr.; ovary sup. or \(\frac{1}{2}\)-inf; fr. with thin pericarp and 1-3 seeds with fleshy coats): Sansevieria, Ophiopogon.

ALETROIDEAE (short rhiz with narrow or lanceolate radical 1.; (P); anthers semi-intr.; caps. loculic.; seeds ∞, with thin

testa): Aletris (only genus).

LUZUR/AGOIDEAE (shrubs or undershrubs with erect or climbing twigs; infl. twigs usu, many-flowered, cymose, rarely iflowered, with scaly bract at base; both whorls of P alike or not: berry with spherical seeds): Luzuriaga, Lapagerra.

XI. SMILACOIDEAE (climbing shrubs with net-veined 1.; fls. small in axillary umbels or racemes or term panicles; loc. with I

or 2 orthotr. or semi-anatr. ovules) Smilax. Liliago (Caesalp.) L. = Anthericum L. (Lili.).

Lilithorae. The 9th order of Monocotyledons. Cf. p. vi.

Lilium Tourn. ex Linn. Liliaceae (v). 60 N. temp. Herbs with scaly bulbs, leafy stems and fls. in racemes. Honey secreted in long grooves at the bases of the P-leaves. The fls. of many sp. are visited by Lepidoptera. L. Martagon L. gives off its scent at night (cf. Oenothera). L. bulbiferum L. is reproduced veg. by bulbils in the In most sp. with hanging fls. the caps. when ripe stands upwards, so that the seeds can only escape when it is shaken. Many sp. of lily cult. orn. fl.

Limaciopsis Engl. Menispermaceae. 1 trop. Afr.

Limatodes Lindl. (Phajus p.p. BH.). Orchidaceae (II. 9). Crossed by Preplanthe vestita is the Calanthe Veitchii Hort.

Limb, the free portion of a concrescent corolla; one branch of a sympodium.

Lime, Citrus Medica L., var. acida, var. Limetta, Tilia; - myrtle (W.I.), Triphasia.

Limeum L. Phytolaccaceae (Aizoaceae BH.). 15 S. Afr. to India. Limit of trees, either N. or S., or upwards in the Mts., beyond which they do not naturally occur.

Limivasculum Borner = Carex p.p. (Cyper.).

Limnanthaceae (EP.; Geraniaceae p.p. BH.). Dicot. (Archichl. Sapindales). A very small fam. (2 gen., 5 sp., N. Am.) sometimes united to Geraniaceae, but with the ovules as in ord. Sapindales. Herbs with exstip. alt. 1. and reg. \$ fls., 3—5-merous, with two whorls of sta. Ovary 3-5-loc., ovules 1 in each loc., ascending, the micropyle facing outwards and downwards. Fruit a schizocarp. Seeds exalbuminous. Genera: Limnanthes, Floerkea.

Limnanthemum S. P. Gmel. Gentianaceae (II). 20 trop. and temp. L. (Villarsia) nymphaeoides Hoffmgg. et Link, S. England, is a waterplant with habit of Nymphaea. The infl. appears to spring from the top of the leaf-stalk, but really the floating it springs from the infl. axis. This is an advance upon the Nymphaea construction, as the materials going from 1. to seeds have not to travel to the bottom of

the pond and up again.

Limnanthes R. Br. Limnanthaceae. 4 Pacific N. Am.

Limnas Trin. Gramineae (8) 1 E. Siberia.

Limnia L. (Claytonia Gronov.). Portulacaceae. 10 N. Am.

Limnobium Rich. (Hydromystria G. F. W. Mey., Trianea Kaist.). Hydrocharitaceae. 3 Am. L. (H.) stoloniferum Griseb. (T. bogotensis Karst.), a small floating plant often cult. It reproduces veg. by 'runners' (cf. Hydrocharis). Its root-hairs are used to show circulation of protoplasm. Only the 2 pl. is known in Eur.

Limnocharis Humb. et Bonpl. Butomaceae. 2 trop. S. Am., W.I.

Limnochloa Beauv. ex Lestib. = Eleocharis R. Br. (Cyper.).

Limnodium (Cl.), a salt marsh formation.

Limnophila R. Br. (Ambulia Lam. EP.). Scrophular. (II. 6). 30 palaeotrop.

Limnophyton Miq. Alismaceae. 2 palaeotrop.

Limnorchis Rydberg (Habenaria p.p.). Orchid. (II. I). 24 N. Am.,

Limnosipanea Hook. f. Rubiaceae (1. 3). 4 S. and C. Am. Limodorum (Tourn.) L. Orchidaceae (11. 2). 1 S. Eur. A leafless saprophyte with no chlorophyll (cf. Epipogum). The 4 lat. sta. are sometimes fertile.

Limonia L. Rutaceae (V). 10 trop. Afr. and As. Some have thorns in the leaf-axils (1. of branch, as in Cactaceae). The fr. of L. acidissima L. is used in Japan as a substitute for soap.

Limoniastrum Moench. Plumbaginaceae. 3 Medit.

Limonium Tourn. ex Mill. = Statice L. (Plumbag.).

Limosella L. Scrophulariaceae (11. 6). 7 cosmop. L. aquatica L.,

mud-wort, in Brit. multiplies by runners.

Linaceae (EP.; BH. add Erythroxylaceae). Dicot. (Archichl. Geramales). 9 gen., 150 sp., cosmop. Most are herbs and shrubs with alt. entire often stip. l. Infl. cymose, a dichasium or cincinnus, the latter usu straightening out very much and looking like a raceme. Fl. &, reg., usu. 5-merous. K 5, quincuncial; C 5, imbr. or conv.; A 5, 10 or more, often with stds., united at base into a ring; G (2—3—5), multi-loc., often with extra partitions projecting from the midribs of the cpls., but not united to the axile plac.; ovules 1 or 2 per loc., pend., anatr., with the micropyle facing outwards and upwards. Septic. caps., or drupe. Embryo usu. straight, in fleshy endosp. Linum (flax, linseed) is economically important. Chief genera: Radiola, Linum, Hugonia. [BH. chars. incl. ov. 1-loc.]

Linaloa, Bursera delpechiana Poiss. (Mexico).

Linanthus Benth. (Gilia p.p.). Polemoniaceae. 55 N. Am. Linaria Tourn. ex Mill. (BH. incl. Cymbalaria Medic., Elatine Rupp., Elatinoides Wettst.). Scrophulariaceae (II. 3). 100 * and S. Am., chiefly extra-trop. 7 in Brit. (toad-flax), esp. L. vulgaria Mill. (yellow toad-flax). The pl. is a perennial, each year's growth arising from an adv. bud upon the summit of the root. The fl. is closed at the mouth; honey is secreted by the nectary at the base of the ovary and collects in the spur. The only visitors are the larger bees, which are able to open the fl., and whose tongues are long enough to reach the honey. Peloria of the fl. is frequent; a term. fl. appears upon the raceme and is symmetrical, with 5 spurs upon the C and a tubular Sometimes fls. of this type occur all down the raceme. Another interesting sp. is L. Cymbalaria Mill., the ivy-leaved toadflax, found on walls in Brit. Before fert, the fls. are positively heliotropic and stand erect; after it they become negatively heliotropic and bend downwards, seeking out the dark crannies in the substratum, where the seeds ripen.

Wiesner, Die Rohstoffe des Pflanzenreichs. Leipzig. Willis, Agriculture in the Tropics. Cambridge, 1922.

Numerous more special works are mentioned under different heads throughout the book.

Lithobium Bong. Melastomaceae (1). 1 Minas Geraes.

Lithocardium L. = Cordia L. (Borag.).

Lithophragma Torr. et Gray (Tellima R. Br. p.p.). Saxifragaceae (1). 15 N. Am.

Lithophytum T. S. Brandegee. Solanaceae? 1 California.

Lithospermum (Tourn.) L. Boraginaceae (IV. 4). 50 temp.; 3 in Brit. (gromwell).

Lithraea Miers. Anacardiaceae (3). 3 S. Am.

Litobrochia Presl = Pteris L.

Litosanthes Blume. Rubiaceae (11. 5). 3 Malay Archipelago.

Litsea Lam. Lauraceae (II). 180 trop. As., Austr. L. and bark medicinal.

Littledalea Hemsl. Gramineae (10). 1 Tibet.

Littonia Hook. Liliaceae (1). 7 S. and trop. Afr. Like Gloriosa.

Littoralis (Lat.), growing on the beach.

Littorella Berg. Plantaginaceae. 2 sp., 1 in S. Am., and L. lacustris

L. (shore-weed) in Eur. (incl. Brit.). This pl. exhibits two forms, one in water, another on land. The land form has a rosette of narrow l. about 3 cm. long, which spread out upon the ground and show distinct dorsiventral structure. Fls. in groups of 3, one & on a long stalk between two sessile ?, which are ripe before the sta. emerge from the former. Both sta. and style are very long and the fls. are wind-pollinated. Fr. a nut. The water form has much larger l. which grow erect and are cylindrical (centric) in form and internal structure; no fls. are produced, but the plant multiplies largely by runners. It is often mistaken for Isoetes. Live-long, Sedum.

Liveus (Lat.), pale lead colour.

Livistona R. Br. Palmae (1. 2). 20 Indomal., Austr. Tall trees with fan leaves and panicles of \$ fls. Fr. a berry.

Lizard's tail (Am.), Saururus.

Llagunoa Ruiz et Pav. Sapindaceae (11). 2 Andes.

Lianosia Blanco (Ternstroemia p.p.). Theaceae. 1 Phil. Is.

Llavea Lagasca. Polypodiaceae. 1 trop. Am. Llavea Liebm. Inc. sed. 2 Mexico.

Lloydia Salisb. Liliaceae (v). 20 N. temp.; 1 on Snowdon. Loasae Adans. Loasaceae. 100 Mexico and S. Am., chiefly Mts. of Chili and Peru. Several cult. orn. fl.; they possess stinging hairs. The fls. are generally yellow and face downwards. The nectaries. formed of combined stds. (see fam.), are large and conspicuous. The petals are boat-shaped and conceal the groups of sta.

Lousaceae (EP., BH.). Dicotyledons (Archichl. Parietales; Passi-florales BH.). 13/250. Andine plants (cf. Kissenia), many cult. orn. fl.

Mostly herbs, frequently twining, with opp. or alt., rarely stip., I. The epidermis bears hairs of various kinds; esp. common are grapplehairs and stinging-hairs. Fls. usu. in cymes, often sympodial, yellow (rarely white or red), \$\,\ usu. 5-merous. Receptacle deeply hollowed out, so that the fl. is epig. K 5, imbr.; C 5, free or united; A 5-0. In the genera with ∞ sta. there is much difference as to the arrange-In Mentzelia they are evenly distributed round the style, the outermost in some sp. being sterile. In other gen. it is the antesepalous sta. that are sterile, and in some, e.g. Loasa, Blumenbachia, 3 or more of the stds. are united to form a large coloured nectary, whose mouth is towards the centre of the fl. and partly obstructed by the other stds. G 1 or more commonly (3-5), with parietal plac.; ovules 1, several, or ∞, anatr., with one integument; style simple. Fr. various, often a caps., sometimes spirally twisted. Endosp. or not. Chief genera: Gronovia, Mentzelia, Loasa, Blumenbachia. **Loaseae** (BH.) = Loasaceae.

Lobe (l.), portion of a divided (not cpd.) l. or stigma.

Lobella Plum. ex L. Campanulaceae (III). 220 trop. and temp.; 2 in Brit., one in lakes (L. Dortmanna L.); several cult. orn. fl. The fl. (see fam.) is twisted upon its axis through 180°, and is +. The anthers are syngenesious as in Compositae, and the style pushes through the tube thus formed, driving the pollen out at the top. Finally it emerges, the stigmas separate, and the ? stage begins. [See fam. and cf. Campanula, Phyteuma, Jasione and Compositae.]

Loblolly bay, Gordonia Lasianthus L.; - pine, Pinus Taeda L.; - sweetwood (W.I.), Sciadophyllum; - tree (W.I.), Cupania, Pisonia.

Lobogyne Schlechter. Orchidaceae (II. a. III). 2 New Guinea, Poly-

nesia.

Longi- (Lat. pref.), long. Long-moss, Tillandsia.

Long-tongued insects, bees and Hymenoptera.

Lonicera L. Caprifoliaceae. 100 *. L. Periclymenum L. (honeysuckle or woodbine), and others, in Brit. Mostly erect shrubs, a few twining, with opp. frequently connate l. In the axils of many (e.g. L. tatarica L.) are serial buds, of which the lowest gives rise to the fls. usu. in pairs, the central fl. of the small dichasium not being developed. The fl. is frequently +, and gives rise to a berry. some the pair of fls. produces two independent berries, in others the berries fuse into one as they form. Some sp. exhibit the 'fusion' even earlier; and one finds two corollas seated upon what at first glance appears a single inf. ovary. Dissection shows that in most cases the two ovaries are side by side, free from one another, in a common hollow axis; in a few cases, however, the union is more complete. The fl. of the honeysuckle is visited chiefly by hawk-moths (at night). The fl. opens in the evening, the authers having dehisced shortly before this. The style projects beyond the anthers. The fl. moves into a horiz, position at the same time. At first the style is bent downwards and the sta. form the alighting place for insects. Later on the style moves up to a horiz, position, the sta. shrivel and bend down, and this is complete by the second evening when the next crop of buds is opening. At the same time the fl. has changed from white to yellow. The length of the tube keeps out all but very longtongued insects (class F).

Loofah. Luffa cylindrica M. Roem.

Looking glass tree, Heritiera littoralis Ait.

Loose pollen mechanism, cf. Acanthus, and Bartsia, Borago, Calluna, Cyclamen, Erica, Ericaceae, Euphrassa, Galanthus, Melampyrum, Pedicularis, Scrophulariaceae, Solanum.

Loosestrife, purple, Lythrum, yellow, Lysimachia.

Lopezia Cav. Onagraceae (2). 15 C. Am. Fl. +. The two upper petals are bent upwards a little way from the base, and at the bend there seems to be a drop of honey. In reality this is a dry glossy piece of hard tissue; like the similar bodies in Parnassia it deceives flies. There are real nectaries at the base of the fl. There are two sta., of which the post only is fertile; it is enclosed at first in the ant. one, which is a spoon-shaped petaloid std. In the early stage of the fl., the style is undeveloped and insects alight on the sta.; later the style grows out into the place first occupied by the sta., which now bends upwards out of the way. In L. coronala Andr., &c. there

is an upward tension in the sta., a downward in the std., and an explosion occurs when an insect alights. Cult. orn. fl. Lophacme Stapf. Gramineae (11). 1 S. Afr. Lophactis Rafin. Loranthaceae (EP., BH.). Dicots. (Archichl. Santalales; Achlamydosporae BH.). 30 gen., 520 sp., trop. and temp. The only genus in Brit. is Viscum, the mistletoe. An interesting fam. of parasites with green l. Mostly small semi-parasitic shrubs attached to their hosts by suckers or haustoria—usu. regarded as modified adv. roots. A few root in the earth, e.g. the W. Austr. Nuytsia, which grows into a small tree 30 feet high. Most are fairly omnivorous in their choice of hosts, but a few are restricted to one or two. Where the parasitic root joins the host, there is not uncommonly an outgrowth, often of considerable size and complicated in shape. The parasitic root often branches within the tissue of the host, as in mistletoe. The stem is

sympodial, often dichasial, e.g. in Viscum, and the l. usu. evergr. and

leatherv.

Inf. cymose, the fls. usu. in little groups of 3 (or 2, by abortion of the central fl.). When the fls. are stalked, the bracts of the lateral fls. are always united to their stalks, up to the point of origin of the fl. (see Viscum and Loranthus). Infl. sometimes in spikes, with the fls. on the internodes as well as on the nodes.

The recept. is hollowed out, and the P springs from its margin. In the Loranthoideae there is below the P an outgrowth of the axis in the form of a small fringe—the calyculus. Some look upon it as a K, many as an outgrowth of the axis; and this is perhaps the safest view. Peither sepaloid or petaloid. Fls. For unisexual. Sta. as many as, and (as in Proteaceae) united with, the P-leaves. The pollen is often developed in a great number of loculi, separate from one another, though often becoming continuous when mature. Ovary 1-loc., sunk in, and united with, the receptacle, the ovules not differentiated from the placenta. Embryo-sacs > one, curiously lengthened (cf. Casuarina). Fr. a pseudo-berry or -drupe, the fleshy part really the receptacle. Round the seed is a layer of viscin, a very sticky substance. [For full details of the many interesting features of this fam., the infl., fl., pollen, development and structure of ovule and embryo-sac, fruit, seed, germination, haustoria, &c., see Engler in Nat. Pfl. and papers by Wiesner in Sitz. k. Akad. Wien, CIII. 1804, and Keeble in Trans. Linn. Soc. v. 1806.1

Classification and chief genera (after Engler):

I. LORANTHOIDEAE (with calyculus): Struthanthus, Loranthus, Psittacanthus.

II. VISCOIDEAE (without calyc.): Arceuthobium, Viscum.

Diagram of Loranthus (after Eichler). c, calyculus.

Loranthus L. Loranthaceae (1). 350 | * trop. and subtrop. Semiparasites. § or unisexual fls. in small cymes, the bracts adnate to the peduncles. Fr. like that of Viscum. See Nat. Pfl., Eichler's Bluthendiag. and papers by Wiesner and Keeble (cf. fam.).

Lotus (Tourn.) L. Leguminosae (III. 5). 15 temp. Eur., As., S. Afr., Austr. L. corniculatus L., bird's foot trefoil, and others, in Brit. The floral mechanism (class H) is typical of many of the fam. (q.v.). The keel is united above and below, leaving only a small opening at the apex. The pollen is shed in bud into the tip of the keel, and the filaments of five sta, thicken out below the anthers, together forming a piston, which, when the keel is depressed, forces the pollen out in a stream at the apex. The style is immersed in the pollen, but only becomes receptive on being rubbed, so that the fl. has a chance of cross-fert. The plant is useful for pasturage.

Lycopersicum Hill. (Solanum p.p. EP.). Solanaceae (2). 10 S. Am. L. esculentum Mill. (Solanum Lycopersicum I.) is the tomato or

love-apple.

Lycopodiaceae. Lycopodiales, Eligulatae. 2 gen., 190 sp., trop. and temp. The fertilised ovum gives rise directly to the leafy plant; the embryo has a suspensor and a foot; and its upper part at fist forms a tuber-like organ, the protocorm, from which the l. and stem develope. In P. the stem is short and unbranched, in L. long and much branched, bearing small simple l., and roots developed in acropetal succession. The sporangia are axillary, and form as a rule a dense terminal cone or strobilus. The spores are all of one kind and give rise on germ. to fairly large monoec. prothalli.

Classification and genera:

Small pl. with a few rad. l. and head of sphorophylls on leafless stalk:

Phylloglossum.

Larger pl. with no rad. l. and sporophylls on leafy stalk:

Lycopodium.

Lycopodiales. One of the main divisions of Pteridophyta. Mostly leafy plants, with well developed stems and small unbranched l. The sporophylls are usu. massed together into cones, recalling those of the Gymnosperms. Sporangia single at base of l. on upper side, or in axil, 1-loc. They are classified as follows.

A. ELIGULATAE (eligulate: spores all alike).

B. LIGULATAE (l. with ligules: spores of two kinds).

Lycopodium L. Lycopodiaceae. 185 trop. and temp.; 5 in Brit., chiefly in mountain districts (club-mosses). The commonest is L. clavatum L. (often called stag-horn moss); the others are L. Selago L., L. alpinum L., L. annotinum L., and L. inundatum L. All but the last are xero. evergr. pl. with hard wiry l. The stem branches frequently, apparently dichotomously, but in reality usu. in a monopodial manner. Upon it are borne the roots, which branch dichotomously, and are developed in acropetal succession. The l., narrow and unbranched, are usu. placed spirally upon the stem, but in some form four ranks, as in most Selaginellas. Many have veg. repr. by small bulbils in the l. axils. [Prothalli, see Bruchmann in Bot. Zeit. 1899, p. 6.]

Sporangia all alike in structure, containing spores of one kind only; placed upon the bases of l. which are usu. crowded together to form a terminal spike or strobilus. In L. Selago some or all of the sporangia are often replaced by small bulbils (cf. Polygonum vivi-

parum, Allium sp., Globba, &c.).

Lycopsis L. Boraginaceae (IV. 3). 3 Eur., As. L. arvensis L., small bugloss, in Brit.

Lycopus Tourn. ex L. Labiatae (VI). 10 N. temp. L. curopaeus L., gipsywort, in Brit.

Lygodisodea Ruiz et Pav. (Paederia p.p. EP.). Rubi. (II. 6). 4 trop. Am.

Lygodium Sw. Schizaeaceae. 25 trop. and subtrop. Twining ferns. The stem remains comparatively undeveloped, but the I. has unlimited apical growth, and the long midrib twines around supports like the stem of the hop, bearing pinnae at intervals. The l. are borne on the stem in one dorsal row. The sporangia are in a double row on the back of the fertile pinnae, and each is surrounded by a cup-like indusium.

Lythraceae (EP.; BH. incl. Ohn., Punic., Sonnerat.). Dicots. (Ar-
  chichl Myrtiflorae). 21 gen., 500 sp., all zones but frigid. Herbs.
  shrubs, or trees; I. usu. opp., entire, simple, with very small stipules or
  none. Ils. in racemes, panicles, or dichasial cymes, $, reg. or 1, usu. 4-
  or 6-merous The axis ('calyx-tube') is hollow, generally tubular. The
  sepals are valvate, and frequently possess an epicalyx, formed, as in
  Potentilla, of combined stips. Petals crumpled in bud, sometimes
  absent. Sta. inserted (often very low down) on calyx-tube, typically
  twice as many as sepals, but sometimes fewer or ∞. G with simple
  style and usu. capitate stigma; 2-6-loc., at the base at least, rarely
  1-loc. with parietal placenta. Ovules usu. ∞, anatr., ascending. The
  fls. of Lythrum (q.v.) and others are heterostyled. Dry fr., usu. cap-
  sular. No endosp. A few yield dyes (Lawsonia, &c.), or are medicinal.
   Chief genera: Peplis, Lythrum, Cuphea, Lagerstroemia
Lythrum L. Lythraceae. 23 cosmop.; 2 in Brit., incl. L. Salicaria L.
  (purple loosestrife). The 6-merous fls. are sol. or in small axillary
  dichasia like Labiatae. Each has 12 sta. in two whorls of different
  length, and the style again is of different length to any of the sta.
  Three forms of fl. occur (trimorphism), each on a separate pl.; they
  are distinguished as long-mid- and short-styled fis. The diagram illus-
  trates the arrangement of parts (S = stigma,
                                                S.
                                                                   A,
  A = anthers, B = base of fl.), as seen in side
                                                                   A2
  view. It is evident that an insect visiting
                                                Αı
  the fis. will tend on the whole to transfer
                                                B
                                                                   В
  pollen from A<sub>2</sub> to S<sub>3</sub>, A<sub>2</sub> to S<sub>2</sub>, A<sub>1</sub> to S<sub>1</sub>, long-
                                                        mid-
                                                                 short-
  rather than from sta. of one length to style
                                              styled
                                                       styled
                                                                 styled
  of another, for it will enter these fls. in the
  same way and to the same depth. The sta. and style project so far
  that an insect can alight directly upon them. Darwin (Forms of
  Flowers) showed by a long series of experiments that the best results
```

are obtained by pollinating S₂ from A₃, or S₁ from A₁, &c., i.e. by

crossing two plants. The number of seeds thus obtained is much greater and their fertility higher than if S_2 or S_1 be fertilised from A_3 , or any other such union be made. Fertilisation of a stigma by sta. of corresponding length Darwin terms legitimate, by sta. of a different length illegitimate. The offspring of illegitimate fert, are few, and have the sterility and other sexual characters of hybrids. As in nearly all other heterostyled pl., the longer the sta, the larger the pollen grains, and the longer the style the larger the papillae of the stigma.

Malpighia Plum. ex L. Malpigh. (11). 30 trop. Am., W.I. Erect pl.; some with stinging hairs, some with cleist. fls.

Malpighiaceae (EP., BH.). Dicots. (Archichl. Geraniales). 55 gen., 650 sp., trop., esp. S. Am. Shrubs or small trees, usu. climbing, forming a marked feature among the trop. lianes. Stem-anatomy peculiar. L. usu. opp., entire, stip., frequently gland-dotted; pl. usu. covered with peculiar branched unicellular hairs. Infl. racemose. Fl. §, obliquely . K (5), imbr., often with large glands at the base of (outside) the sepals; C 5, petals usually clawed, imbr.; A 5+5, obdiplost., often fewer, joined in a ring at the base; anthers opening intr. by longitudinal splits; G (3), obliquely placed in the fl., 3-loc. with axile plac.; one ovule in each loc., pend., semi-anatr., with ventral raphe. Fr. typically a schizocarp breaking into 3 mericarps, but frequently one or more of the loc. abort. The mericarps are often winged, in some cases, e.g. Banisteria, like those of Acer. Seed exalbum.

Classification and chief genera (after Niedenzu):

I. PYRAMIDOTORAE (torus pyramidal; mericarps usually winged): Tetrapteris, Banisteria, Acridocarpus.

II. PLANITORAE (torus flat or concave; mericarps not winged): Malpighia, Bunchosia, Byrsonima.

Malt, barley steeped to start germ., and then kiln-dried. Maltebrunia Kunth. Gramineae (6). 2 Madag., S. Afr.

Malus Tourn. ex L. = Pyrus Tourn. p.p. (Ros.).

Malva (Tourn.) L. (BH. excl. Callirhoe Nutt.). Malvaceae (2). 30 N. temp.; 3 in Brit. Fl. of the ordinary type of the fam., with ocpls. Two Brit. sp. M. sylvestris L. and M. rotundifolia L. (large and small mallow) afford a contrast in floral mech., &c. Honey is secreted in little pockets in the recept., covered with hairs which exclude rain and very short-tongued insects. The large mallow is very protandr.; the sta. stand up at first in the middle of the fl., and afterwards bend outwards and downwards whilst the styles lengthen and occupy the original positions of the sta. The small mallow has much smaller fls., much less visited by insects; they go through stages similar to those described above, but at the end of the ? stage the styles bend downwards, twist in among the anthers and pollinate themselves.

The l. in autumn may usu. be seen covered with brown spots caused

by the fungus Puccinia malvacearum (cf. Berberis).

Malvaceae (EP.; B.H. incl. Bombacaceae). Dicots. (Archichl. Malvaces). 35 gen., 700 sp., trop. and temp. Herbs, shrubs, or trees, with alt. stip. l. Fls. sol. or in cpd. cymose infls. made up of cincinni, ₹, reg., usu. 5-merous. Epicalyx often present; probably an aggregation of bracteoles, but perhaps stipular like that of some Rosaceae (q.w.). K 5 or (5), valvate; C 5 conv., the petals usu. asymmetrical; A usu. ∞, owing to branching of the inner whorl of sta. (the outer is usu. absent), all united below into a tube which is joined to the petals and at first sight makes the C appear gamopetalous; the anthers are monothecous (i.e. each=half an anther), the pollen grains spiny. G (1-∞) frequently (5), multi-loc., with axile placentae. In § I a division of the cpls. by horiz. transv. walls occurs, producing vertical rows of one-ovuled portions. Ovules 1-∞ in each cpl., anatr., usually ascending, sometimes pend. Malva-

viscus has a berry, the rest of the order dry fr., either caps. or schizocarps. Embryo usually curved, surrounded by endosp. The fls. are generally protandr. (see Malva and Goethea). Gossypium (cotton), Hibiscus, and others are of economic value. Many are garden favourites. [BH chars. incl. l. often palmately lobed or cpd.; A 5— ∞ , free or united, pollen smooth; endosp. little or none.] Classification and chief genera (after Schumann):

A. Cpls. in vert. rows.

1. Malopeae: Malope, Kitaibelia.

B. Cpls. in one plane.

2. Malveae (schizocarp; styles as many as cpls.): Abutilon, Lavatera, Althaea, Malva, Anoda.

3. Ureneae (schizocarp; styles twice as many as cpls.):

Urena, Goethea, Pavonia.

4. Hibisceae (capsule): Hibiscus, Gossypium.

Manglietia Blume (Magnolia p.p. EP.) Magnoliaceae. 3 Indomal.

Manglilla Juss. = Myrsine L. (BH.) = Rapanea Aubl.

Mango, Mangifera indica L.

Mangonia Schott. Araceae (VII). I Brazil.

Mangosteen, Garcinia Mangostana I..

Mangroves, the association of pl. of the muddy swamps at the mouths of rivers and elsewhere in the trop, over which the tide flows daily, leaving the mud bare at low water; chiefly |*. Chief gen. Phizophora; others are Acanthus, Aegiceras, Avicenma, Binguiera, Carapa, Cerrops, Conocarpus, Laguncularia, Kandelia, Lumnitzera, Scyphiphora, Sonneratia, &c. Usu. much branched, with aerial roots, both flying buttress and pillar roots; aerating roots rise from the mud in Avicennia, Binguiera, Sonneratia, &c. Many show viviparous germination.

Manicaria Gaertn. Palmaceae (IV. I). I trop Am, W.I.

Maniçoba rubber Gaertn., Manihot Glaziovii Muell.-Arg.

Manihot Tourn. ex Adans. Euphorbiaceae (A. II. 4). 150 S. Am. to Mexico. Shrubs and herbs with monoec. fls. M. Glaziovii Mull.-Arg. and other sp. show bud-protection well. The petiole of the young leaf curls upwards and inwards, so that the leaf is brought above the bud. M. utilissima Pohl is the bitter, M. Aipi Pohl (M. palmata Mill.-Arg.) the sweet cassava or mandioc; both are extensively cult. in the trop. for their large tuberous roots, which contain much starch, &c., and form a valuable food-stuff. The bitter cassava is the one usually cult.: its poisonous juice is squeezed out, and finally dissipated in the drying. The ground roots form mandioc or cassava meal, sometimes called Brazilian arrowroot. By a special mode of preparation, tapioca is prepared from the root. The poisonous juice, evaporated to a syrup and thus rendered harmless, forms an antiseptic, known as cassareep, used in preserving meat, &c. M. Glaziovii is the Ceara rubber; rubber is obtained by tapping the stem of the tree in the usual way. Several other sp. also yield rubber.

Maranta Plum. ex L. Marantaceae. 30 trop. Am. The stds. β γ (see fam.) are present in many. The rhiz. of M. arundinacea L. furnishes West Indian arrowroot, prepared by grinding and washing to free the starch.

Marantaceae (EP.: Scitamineae p.p. BH.). Monocots (Scitamineae). 27 gen., 300 sp. trop., chiefly Am. Herbaceous perennials of various habit, resembling Zingiberaceae, but at once distinguishable by the presence of a swollen pulvinus or joint at the junction of petiole and leaf-blade. L. 2-ranked, sheathing; one side of the l. is larger than the other and is covered by it when the l. is rolled up in the bud. Fls

usu. upon the leafy shoots, in pairs in the axils of the bracts, either one pair or many (cymose, drepania). The fl. is asymmetric, but in each pair the one is complementary to the other (i.e. like its reflection in a glass). Fl. &, pentacyclic. 3-merous. P 3 + 3, clearly distinguished in most cases into calyx and corolla. As in the allied fams., the A is united to the C. There is one fertile sta., often petaloid, and round it various petaloid structures (cf. carefully Canna The labellum of and Zingiberaceae). Canna is represented by a hood-shaped l. covering the style (Kapuzenblatt). The staminode a is repres. by a more or less leathery or callous 1. (Schwielenblatt); B and γ are not always present, but are petaloid when they do occur. The same views as to

Floral diagram of Maranta bicolor (modified from Eichler). αβγ, staminodes; L., labellum (Kapuzenblatt).

the morphology of these structures have been proposed as in the case

of Canna q.v.). \overline{G} (3), typically 3-loc. 3 ovuled, but commonly 2 of the loc. are abortive (as in fig.) and the third contains one ovule; ovule ana-campylo-tropous: style curved and at first enclosed in the 'Kapuzenblatt' or hood. The fl. often has an explosive mechanism. The pollen is shed upon the style, which remains held in the hood. Insects enter upon the staminode a, and in sucking honey (secreted by glands in the septa of the ovary) set free the style, which descends with a sudden shock, touching the insect's back and at the same time showering the pollen upon it (cf. Genista). Fr. usu. a loculic. caps. Embryo curved, in perisperm. Seed often arillate. Maranta and others furnish arrowroot, &c. Chief genera: Calathea, Maranta, Thalia.

Marantochloa Brong. ex Gris. Marantaceae. 1 Réunion.

Marasmodes DC. Compositae (7). 3 Cape Colony.

Marathrum Humb. et Bonpl. Podostemaceae. 8 trop. Am.

Marattia Sw. Marattiaceae (2). 30 trop. and N.Z. The synangium is oval and the compartments open by slits into a central space.

Marattlaceae. The only fam. of Filicales. Marattlales. 7/150 trop. and subtrop. Large ferns; stem stout usu. erect, rarely > 2' long and seldom branched; strongly dorsiventral in Protomarattia and Christensenia. L., often very large, ovate, simply or compoundly pinnate, with circinate vernation. L.-base with stipular enlargements connected by transverse commissure. The r. arise at the growing point, one or more to each l., burrowing obliquely outwards.

Sori intramarginal on lower side of l., strictly circumscribed with no definite indusium. All have a simple series of sporangia radiately disposed round a central receptacle, linear or point-like as sorus is elongated or circular. The sporangia may be free from one another, or combined to form synangia. Spores all of one kind, though sometimes varying in shape, giving rise to monoec. prothalli like those of

ordinary ferns, but large and capable of somewhat long life. Classification and Genera:

Leaf ovate or pinnate; venation simple, dichotomous.

Sporangia separate: Angiopteris (l. compound pinnate), Macro-glossum, Archangiopteris (ovate or once pinnate).

Synangia: Marattia (cpd. pinnate), Protomarattia, Danaea (simple or once pinnate).

Leaf palmate, with 5 nearly equal lobes; venation reticulate: Christensenia.

Cf. Bower, Ferns, ii, 95. Seward in Linn. Jl. 1922 (Hooker lecture). Marcellia Baill. Amarantaceae (2). 2 trop. W. Afr.

Marshallia Schreb. Compositae (5). 5 S. U.S.

Marsilea L. Massileaceae. 60 trop. and temp. Rhiz. bearing 1. at the nodes, and roots on the lower side. L. petiolate with four lobes, resembling those of '4-leaved clover.' They 'sleep' at night like Oxalis. In some they are floating, on delicate petioles; others grow in shallow water, the 1. standing erect. Some, e.g. M. vestita Hook. et Grev., vegetate during the wet season, and pass the dry in the form of sporocarps.

The sporocarp is a bean-like structure attached to the petiole of the l. by a stalk. It contains a number of sori, each forming a chamber reaching from the ventral to the dorsal edge of the sporocarp. In each sorus on the outer side is a placenta in the form of a ridge bearing micro-sporangia on its sides and mega-sporangia on the top. The latter contain one spore each. The sporocarp is very hard and may remain in water a long time without showing any effect. Ultimately however, or at once if the hard shell be injured, a swelling of the mucilaginous interior tissue bursts it. "As more water is absorbed, this gelatinous inner tissue continues to expand, and forms a long worm-shaped body to which are attached a number of sori, each surrounded by a sac-shaped indusium in which the sporangia are closely packed" (Campbell). The spores are finally set free by the dissolution both of indusium and sporangium wall. The prothalli are similar to those of Salviniaceae.

The sporocarps of some are eaten by the natives of Austr. (nardoo). Marsileaceae. Filicales Leptosporangiatae. A fam. of 2 gen., 65 sp. trop. and temp. Mature pl. aquatic or amphibious with thin creeping stem, growing by an apical cell, and bearing l. at distinct nodes. L. circinate in vernation like those of ordinary ferns, but varying much in type (see gen.). Roots are formed from the lower side of the stem.

Sporangia in sporocarps, which are complex structures not homologous with those of Salviniaceae. Each is the equivalent of a leaf-segment and encloses several sori, the latter composed both of microand mega-sporangia. Each spore is furnished with an epispore of hardened frothy mucilage. The spores pass the winter (or dry season) inside the sporangia. The subsequent stages in the life history resemble those of Salviniaceae. See gen. for details. Classification:

Leaf with 4-partite blade; sporocarp bean-shaped: Marsilea.,, simple; sporocarp spherical: Pilularia.

Mesechites Muell.-Arg. = Echites L. (Apocyn.).

Mesembryanthemum Dill. ex L. Aizoaceae (11). 350 S. Afr. Xero. of the most pronounced kind with very succulent l., usu. closely packed together; the young l. stand face to face at the growing apex till well grown, and thus protect the young bud. In M. obconellum Haw. the pairs of 1. are congenitally united into a fleshy body with a little slit in the centre. Several have thorns, sometimes fl.-stalks hardened after the fall of the fl., sometimes branches, as in M. spinosum L. (the leafy branches appear below these in the next year, in the same axils). Fls. usu. term. on the stems, sol. or in dichasia or cincinni. Outer sta. (due to branching) repres. by numerous petaloid stds., having the appearance of a C. The mature ovary is 5-loc. with parietal plac.; this peculiar feature is due to an excessive growth of the peripheral tissue during development, which gradually turns the loculi completely over (cf. Punica). Fr. a caps. which opens only in moist air, contrary to the usual wont of capsules. Some, e.g. M. edule L. (Hottentot fig), contain an ed. pulp. M. crystallinum L. is the ice-plant, so called because its 1. are covered with small glistening bladder-shaped hairs.

Meso- (Gr. pref.), middle-; -carp, the middle part of a fr. wall; -chil, of a lip; -phyll, of a leaf; -phytes, average plants, suited to a fairly and continuously moist climate.

Mimosa L. Leguminosae (1. 5). 400 trop. and subtrop. Am., a few in Afr. and As. M. pudica L. (sensitive plant) is now a common trop. weed and is cult. in hothouses. Mainly herbs and undershrubs, frequently with stipular thorns. M. pudica has a bipinnate l. with four secondary petioles. It is exceedingly sensitive, and a touch or shake will make it move rapidly into the position which it assumes at night. The leaflets move upwards in pairs, closing against one another, the secondary petioles close up against one another and the main petiole drops through about 60°. After a short time the movements are slowly reversed. They are effected by the aid of a pulvinus or swollen joint at each point of movement. Each pulvinus can be made to work independently of the rest by gentle stimulation, and the propagation of the stimulus from pulvinus to pulvinus may also be The ribs of the fr. are frequently thorny and are usu. dropped on dehiscence. M. bark, bark of Acacias used for tanning.

Mimulopsis Schweinf. Acantoaceae (IV. A). 15 trop. Afr., Madag. Mimulus L. Scrophulariaceae (II. 6). 80 cosmop. M. iuteus L. (yellow monkey-flower) nat. in Brit. M. moschatus Dougl. is the common musk-plant of cottage windows. Insects entering the fl. touch first the stigma, which is sensitive to contact and closes up (cf.

Martynia). Cult. orn. fl.

Mimusops L. Sapotaceae (2). 65 trop M. Balata Crueg. (M. globosa Gaertn.; Guiana) yields a gutta-peicha (balata). M elata Allem. is the Brazilian milk tree or Masseranduba. The timber is hard and durable, the fr. edible, "but strangest of all is the vegetable milk. which exudes in abundance when the bark is cut; it has about the consistence of thick cream." (Wallace, Amazon, ch. 11.) It is used as milk, and for glue.

Monimiaceae (EP., BH.). Dicots. (Archichl. Ranales; Micrembryae BH.). 30 gen., 200 sp., chiefly S. trop., and esp. in the 'oceanic' floral regions (Madag., Austr., Polynes.). Shrubs and trees, with leathery evergr. 1., often resiniferous with aromatic scent, usu. opp., exstip. Fls. sol. or in cymes., perigynous, commonly unisexual, reg.; often the two sexes differ in the hollowing of the axis. Frequently the bud opens by throwing off the outer ends of the P-leaves as a sort of lid. P 4-- o, simple, or o; A o or few, the anthers intr. or extr., opening by slits or valves; G. usu. ∞ , sometimes few or I, each with I usu. basal erect anatr. ovule. Fr. of achenes, often ± enclosed in or borne on a fleshy recept. Embryo straight, in copious endosp. The fam. forms a connecting link between Lauraceae and the other Ranales, being closely allied on one side to L., on the other to Calycanthaceae. Chief genera: Hedycaria, Peumus, Tambourissa, Laurelia. Monixus Finet (Angraecum p.p.). Orchid. (11. 20). 8 trop. Afr.,

Madag.

Moraceae (EP.; Urticaceae p.p. BH.). Dicots. (Archichl. Urticales). 55 gen., 800 sp., trop. and subtrop., a few temp. Most are trees or shrubs with stip. I., and with latex. [See Ficus, Cecropia, Maclura, Humulus.] Infl. cymose, usu. in the form of (pseudo-) racemes, spikes, umbels or heads (cf. Urticaceae, and paper there cited). Fls. unisexual. P usu. 4 or (4), persistent; A in a = 1 and opp. to P, bent inwards or straight in the bud, not exploding like those of Urticaceae; G in ? of (2) cpls. of which one is usu. aborted all but the style; ovary 1-loc. sup. to inf.; ovule 1, pend., with micropyle facing upwards, or rarely basal and erect. Fr. an achene or drupelike; but commonly a multiple fr. arises by union of the frs. of different fls., often complicated by addition of the fleshy common recept. (see Morus, Ficus, Artocarpus). Seed with or without endosp.; embryo usu. curved. Many yield useful fruits, e.g. Morus, Artocarpus, Ficus, Brosimum, &c.; other important economic plants are Broussonetia (paper), Castilloa (rubber), Brosimum (milk), Ficus (caoutchouc, lac, timber, &c.), Cannabis (hemp, ganja), Humulus (hop) and others.

Classification and chief genera (after Engler): I. MOROIDEAE (sta. incurved in bud; ovule apical, anaor amphi-tr.; l. folded in bud; stipules small and not leaving an amplexicaul scar on falling): Morus, Maclura, Broussonetia, Dorstenia.

II. ARTOCARPOIDEAE (sta. straight; ovule as in I.; l. convolute; stipules leaving an amplexicaul scar): Arto-

carpus, Castilloa, Antiaris, Brosimum, Ficus.

III. CONOCEPHALOIDEAE (sta. straight; ovule at base or apex, orthotr. or slightly curved; l. &c., as in II.): Cecropia.

CANNABOIDEAE (sta. short and straight; ovule apical, anatr.; achene; endosp.; herbs with free stipules): Humulus, Cannabis.

Moraea Mill. ex L. Iridaceae (II). 90 Afr., Masc. The outer integument of the ovule becomes fleshy as it ripens. Cult. orn. fl.

Murtonia Craib. Leguminosae (between III. 7 and III. 10). I Burma. Musa L. Musaceae. 80 palaeotrop. Large herbs (to 10 ft.) with rhiz. and 'false' aerial stems (see fam.). The infl. springs from rhiz. and emerges at the top of the aerial 'stem.' Fls. ∞, in the axils of leathery, often reddish-coloured bracts, the fruit-forming ? firs. at the base of the infl. The sepals and two ant. petals are joined into a tube, the post. petal is free; there are 5 fertile sta., except in M. Ensete J. F. Gmel. where the post. sta. is also fertile; the ovary is 3-loc., with ∞ anatr. ovules. Fr. a longish berry. Seeds with mealy perisperm. M. paradisiaca L., the plantain, with its subsp. M. sapientum L., the banana, is one of the most important foodplants, and is everywhere cult. in the trop, and subtrop, yielding much more food per acre than even the potato. The cult. forms are

- A. Banana (Musa paradisiaca, subsp. sapientum) in fruit; the fruits are seen on the lower portion of the peduncle, the upper which bore male flowers is bare, at the extreme end a few spathes remain; much reduced. B. Single spathe with
- a large number of flowers crowded in its axil, reduced.

 C. Male flower of M. Ensets. The posterior median petal is on the right, the remaining five perianth-leaves are represented by the larger strap-shaped trifid limb on the left; the lateral members of the inner whorl are not represented in the incision of the limb.
- D. Upper portion of perianth-limb of M. Cavendishii shewing five lobes, the two smaller representing the lateral members of the inner whorl.

 E. Floral diagram of a bisexual flower of Musa.

 F. Floral diagram of Heliconia metallica.

A, after Redouté. B, C, from Botanical Magazine. D, after K. Schumann. E, F, after Eichler.

propagated entirely from the rhiz. and produce no seeds (cf. Citrus). About 200 different forms are in cult., and some other sp. are occasionally employed. There is a vast trade, esp. to the U.S., from C. Am., Jamaica, Canaries, &c. In Venezuela, &c. alcohol is prepared. The dried fr. are ground to form plantain-meal. The stalk of the infl. of M. Ensete (Abyss.) is cooked and eaten. The leafstalks of M. textilis Née (Philippines, &c.) furnish a useful fibre, known as Manila hemp or abaca. [For details of economic uses, &c., see Kew Bulletin, Aug. 1894.] Cf. Supplement.

Musaceae (EP.; Scitamineae p.p. BH.). Monocots. (Scitamineae). 6 gen., 150 sp. trop. They are (except Ravenala) gigantic herbs with usu, freely branching rhiz, from which the l. spring; the sheaths of the l. are rolled round one another below, and form what looks like an aerial stem, attaining in the banana some yards in height. The l. is large and oval, with a stout midrib, and parallel veins running from it to the edge; it is rolled up in bud. The edge is easily torn between the bundles, as they do not join in the same way as in a Dicot.; and so the wind and rain soon reduce the l. to a very ragged condition. Fls. in cymes or racemes with large brightly coloured bracts or spathes; usu. \(\forall \), exc. Musa, and \(\forall \), but nearer to the usual type of Monocotyledonous fl. than those of other Scitamineae. P 3+3, free or united in various ways, both whorls petaloid; A 3+2, the post. sta. repres. by a std.; $\overline{G}(3)$, 3-loc., with $t-\infty$ ov. in each loc. Berry, caps., or schizocarp. Seed with straight embyro and mealy perisperm. Fls. rich in honey, and visited by bees and Musa is an important economic genus.

Classification and genera: closely related to the other Scitamineae

(joined by BH.), less closely to Liluflorae and Orchids.

MUSOIDEAE (l. alt., fl. collateral, post. P leaf free): Musa.

STRELITZIOIDEAE (l. in 2 ranks, fl. in cymes, K free): II. Ravenala, Strelitzia, Heliconia.

Myoporaceae (EP., Bil.). Dicots. (Sympet. Tubiflorae; Lamiales BH.). 5 gen., 100 sp. chiefly Austr. and neighbouring Is. (1 in each of following.—Sandw. Is., E. As., Mauritius, Afr., W.I.). Most are trees or shrubs, with alt. or opp. entire exstip. l., often covered with woolly or glandular hairs, frequently very reduced in size. Fls. sol., or in cymose groups, axillary, \$\forall \text{, reg., or \$\dagger\$. K(5), C (5), A 4, didynamous; anther loculi confluent; G (2), 2-loc. or by segmentation 3-10-loc., in the former case with 1-8, in the latter with 1, pend. anatr. ovule in each loc. Drupe. Endosperm. Chief genera: Pholidia, Myoporum.

Myoporineae (BH.) = Myoporaceae.

Myoporum Banks et Soland. Myoporaceae. 25 Austr., E. As., Sandw. Is., Mauritius. M. laetum Forst. f. (N.Z.) yields useful timber.

Myoschilos Ruiz et Pav. Santalaceae. 1 Chili. Myoseris Link = Pterotheca Cass. (Comp.).

Myosotidium Hook. Boraginaceae (IV. I). I sp. Chatham Is.

Myosotis L. Boraginaceae (IV. 4). 35 sp. * temp. 8 in Brit. (scorpion-grass, forget-me-not). The corolla-mouth is nearly closed by scales, and in some there is a coloured ring at the entrance forming a honey guide (see Life of Sprengel, in Nat. Science, Apr. 1803). The colour of the C changes as it grows older (see fam.).

Myosurandra Baill. Hamamelidaceae. 1 Madagascar.

Myosurus L. Ranunculaceae (3). 7 temp. M. minimus L. (mousetail) in Brit. Recept. much elongated.

Myracrodruon Allem. = Astronium Jacq. p p. (Anac). [Ov. ∞ per loc. Myrceugenia Berg. (Myrtus p.p. BH.). Myrt. (1). 15 temp. S. Am. Myrcia DC. ex Guill. Myrt. (1). 500 trop. S. Am, W.I. Acanthaceae (1). 1 palaeotrop. Nelumbium Juss. Nymphaeaceae (1). 2, N. luteum Willd., Pennsylvania to Colombia, and N. speciosum Willd. (N. nuciferum Gaertn.), As. and N.E. Austr. The latter sometimes supposed to be the sacred Lotus, no longer found in the Nile, is sacred in India, Tibet, China, and was introduced to Egypt about 500 B.C. (cf. Nymphaea). Both are marsh plants; the fis., which are very large and handsome, and the big peltate slightly hairy l., stand above the water and do not float upon it. The rhiz. bears 'triads' of leaves; after a long internode comes a scaly-l. on the lower side, then one on the upper side, immediately followed by a foliage-l. with ochreate stipule, then a long This peculiar leaf-arrangement is quite internode again, and so on. unique. From the axil of the second scale-l. springs the fl., from that of the foliage-1. a branch. The fl. has no bracteoles. The first P-leaf is ant., the second post., then follow 2 lat.; these 4 are sometimes regarded as a K. They are followed by numerous petals and sta., acyclically arranged. In the centre of the fl. stands the obconical G, a large number of cpls. embedded separately in the top of the swollen recept. Each contains I pend. ovule. The recept. becomes dry and very light, and the achenes separate from it, as the fruit ripens. It breaks off bodily from the stalk and floats about until decay sets free the fruits, which sink to the bottom of the pond. There is no endosp, or perisperm. The seeds of N. speciosum are used as food in Cashmere, &c. Nelumbo (Tourn.) Adans. = Nelumbium Juss. (Nymph.). Nemacaulis Nutt. Polygonaceae (I. I). I California. Nemacladus Nutt. Nepenthandra Sp. Moore. Euphorbiaceae (A. 11. 5). I Burma. Nepenthes L. Nepenthaceae. 60 palaeotrop. (pitcher plants). Most are herbs growing in boggy places and climbing by aid of tendrils, prolongations of the leaf-midribs. The end of the tendril developes as a rule into a pitcher, with a lid projecting over the mouth, but not closing it except in the young state. The pitcher developes by an invagination of the upper surface of the tip of the 1; the tip takes no part in the development, and the lid grows out below it. The edge of the pitcher is curved inwards; at the entrance are numerous honeyglands, and for some distance below it are other glands, sunk in little pits on the inner surface. Insects attracted by the honey (or by the bright colour) gradually work their way downwards among the glands, and presently get upon the slippery lower part and ultimately into the water at the bottom of the pitcher, where they are drowned. The plant absorbs the products of their decay.

Many are epiphytic. In N. ampullaria Jack there are two kinds of 1. (cf. Cephalotus), some with tendrils and no pitchers; others, as

stalked pitchers arranged in a radical rosette.

Fls. dioec., reg., in racemes or with the secondary branching cincinnal; no bracts. P 2+2; in the & fl. sta. (4—16) in a column; in the & fl. G (4), 4-loc.; ovules ∞ , anatr., in many rows. Capsule leathery, loculuc. Seeds light with long hair-like processes at the ends; embryo straight, in fleshy endosp. Many sp. and hybrids cult. [See Goebel's Pflanzenbiol. Momenclature (with esp. reference to classification). The unit in classification is the species, which was described by A. L. de Jussieu as "the perennial succession of similar individuals perpetuated by generation." All marsh marigolds (Caltha palustris) form one sp., or all pl. of Indian corn (Zea Mays) or coconut (Cocos succifera). But exactly to

define a sp. is impossible. Each man in practice arrives at his own conception somewhere between (or at) the extremes usu. called Linnean and Jordanian sp. Draba (Erophila) verna for example (Linnean) is distinguished from other D. by absence of petiole and oblong elliptical pod, but Jordan, studying the sp. in great detail, split it into a great number of forms, to which he gave specific rank, when he found that each one continued to breed true. These were distinguished by "small" characters, such as differences in hairiness, fruit-shape, leaf-form, &c. Cf. Jordan, Diagnoses d'espèces nouv. ou méconnues,

Paris, 1864, Rosen in Bot. Zeit. 1889, p. 565.

The most popular conception of sp., and the one used in this book, and in most floras and other botanical books, is the Linnean, or somewhere near to it, e.g. as used by Sir J. D. Hooker, or Dr A. Engler. The many forms into which a wide ranging sp. can be divided are classed, the larger and more important as subspecies, the smaller as varieties, subvarieties, and forms. Publication of a sp., by sale or public distribution of printed matter or indelible autographs, consists in the giving of a Latin description of the sp. sufficient to distinguish it from its congeners, and of a name (Latin or Latinised) by which it may be recognised. The name of the author is then appended (often in abbreviated form, cf Abbreviations), and publication is complete. A sp. for example may be viscosa (stricky) Jones, or gigas (giant) Klein.

The next stage above sp. is genus or group of sp., with possible intermediates of subgenus, section and subsection; and again the difficulty crops up as to the comprehensiveness of the group. What one may consider as a subgenus, or even a section, another may regard as a genus. The great thing is to find a group of sp. clearly marked off by two or three distinct chars. from all other groups. Such a genus as the roses (Rosa), the buttercups (Ranumulus), the bananas (Musa), the pineapples (Ananas) or the figs (Ficus) is unmistakeable, and is still defined as it was defined by Tournefort or Linnaeus. But in such a case as Andropogon, Cereus, Eugenia, Loranthus, Myristica, Oenothera, the genus is not so clearly marked off, and does not, thioughout its members, retain a few well-marked chars. constantly, so that a large number of botanists prefer to split it into other smaller genera. Some of those mentioned are often recognised as composed of 5 to 20 genera.

Genera are grouped into families (e.g. Ranunculaceae), these into orders (e.g. Ranales), classes (e.g. Dicotyledoneae), and divisions (e.g. Siphonogama). But subdivision is usu. necessary here, so that the

list of possible headings ultimately runs:

Div., Subdiv., Class, Subclass, Order, Suborder, Fam., Subfam., Tribe, Subtribe, Gen., Subgen., Sect., Subsect., Sp., Subsp., Var.,

Subvar., Form.

To every plant is given a binomial appellation, the first half being the gen., the second the sp., e.g. Ranunculus acris. To complete the identification the name of the author of this name must be appended, in this case Linnaeus (L.), as there might be another plant with the same name given by someone else.

The essential points to aim at are fixity of names, and the avoidance of confusion, but in very many cases these are yet to be arrived at.

A group of any rank can bear only one valid name—the oldest. But to apply this rule rigidly would allow almost no fixity. For flowering plants and ferns it is therefore agreed to go back only to the first edition (1753) of Linnaeus' Species Plantarum, and the descriptions in his Genera Plantarum, edit. 5, 1754. Further, there are a large number of genera whose current names are not the oldest, but are so familiar that a change would cause confusion, so that it has been agreed, for instance, that Welwitschia shall retain that name and not be termed Tumboa, though the latter was first bestowed, and the same in a great number of other instances.

When a name given to a genus by a pre-Linnean author is taken

over by Linnaeus or a subsequent author, it is thus indicated:

Mercurialis (Tourn.) L. (named by T., accepted by L.).

When a name was given, but not published, by a botanist, and subsequently published by another, it is shown thus:

Leersia Soland. ex Sw. (given by Solander, in Ms., and published

by Swartz).

When a name is published by a man writing in someone else's publication, it is indicated by 'in,' e.g. L. C. Rich. in Michx. means

given by Richard in Michaux's Flora.

When a sp. is transferred from one gen. to another, it retains its specific name if possible (*n.e.* usu. if the new gen. does not already contain a sp. with the same name), and the author of the first may be indicated in brackets, *e.g. Cheiranthus tristis* L. may become Matthiola tristis (L.).

Genera and species that are merged in others become synonyms, of which there are vast numbers. This book contains very many generic synonyms, indicated thus:

Acrocarpidium Miq. = Peperomia Ruiz et Pav.

But a synonym may at any time be revived, so that it is not customary to use names from the list of synonyms to designate new gen. or sp.

When a genus is merged in another, the fact is often signified by the letters p.p. (pro parte), to indicate that it only forms a portion of the larger genus, often a subgenus or a section.

The symbol x is used to designate a hybrid (cross of two species)

or mule (cross of two divisions of one sp.).

Generic and specific names as published are collected in the Kew Index, to which a supplement is published every 5 years. At first the names were divided into valid and synonyms, but now all are published without any editorial expression of opinion. In de Dalla Torre and Harms' Genera Siphonogamarum is a list of generic names and synonyms pretty much as accepted by Engler. In this book I have placed all genera as accepted by Linnaeus, Bentham-Hooker, or Engler-Prantl, and all subsequent genera, whether usu. considered synonyms or not.

Nymphaeaceae (III). 7 N. temp. and cold.

N. luteum Sibth. et Sm. (yellow water-lily or brandy-bottle) in Brit. Veg. habit of Nymphaea (q.v.). The fl. projects a little above the water, and is fully hypog. At the base of the peduncle is a rudimentary bract. There are 5 large coloured outer P leaves, quincuncial, the fourth anterior; within are the 'petals,' 13 in number arranged in a 5/13 spiral. Then follow ∞ sta., the outer 13 alt. with the petals, the next 13 with them, and so on in a spiral. G (10-16), multiloc. Stigmas, ovules, &c., as in Nymphaea. Fr. a large berry; it breaks off from the stalk and splits up into separate cpls. The seeds have no aril like Nymphaea, but the slimy pericarp contains bubbles: the seeds are set free by its decay, and sink.

fully parasitic on roots. Cotvledons 3. L. alt.

Nyctaginaceae (EP., BH.). Dicots. (Archichl. Centrospermae; Curvembryae BH.). 20 gen., 160 sp., mostly trop. and esp. Am. Trees, shrubs or herbs with opp. (often unequal) l. and no stips. Fls. in cymes, & or unisexual, and with much variety. At the base of the fls. are usu. several bracts, often large and coloured. In Bougainvillaea a large conspicuous bracts enclose a group of 3 fls. In Abionia the number of bracts and fls. is larger, while in Mirabilis there is only one fl. and the involucre resembles a calyx. P usu. (5), petaloid, persistent upon the ripe fr.; usu. the upper part drops away and the fr. remains in the lower part, which is termed the anthocarp, and may become glandular, or form an umbrella-like wing, or otherwise serve for seeddispersal. A typically 5, alt. with the P, but often 3, 8, 10 or other numbers, or raised to 20 or 30 by branching; filaments often of unequal length; G 1, with long style and 1 basal erect ana-campylotr. ov. Achene enclosed in the P. The N. are of slight economic value: see Mirabilis, Neea, &c. Chief genera: Mirabilis, Bougainvillaea, Pisonia, Neea, Reichenbachia.

Nymphaea (Tourn.) L. (Castalia Salisb.). Nymphaeaceae (III). 40 trop. and temp. N. alba L. (white water-lily) in Brit. Many cult., e.g. N. Lotus L. considered to be the original sacred lotus of Egyptics (see Nelumbium). They grow in shallow water. There is a stout creeping rhiz.; at the tip it is bent up, and bears stip. l. and fls. on long stalks. The peduncle occupies the position of one of the l. of the spiral, and there is no bract at its base. The l. is large and floats on the surface; it is nearly circular, entire, and leathery, with stomata, cuticle and palisade tissue on the upper side.

Fl. &, reg., acyclic; floats on the surface. The 4 outermost floral l. exhibit a peculiar aestivation, the ant. being entirely outside, the post.

inside the lat. 1. Most authors regard them as K, but Caspary (Eichler, Blütendiagr., II. 184) regards the anterior 1. as bract adnate to peduncle (cf. Solanaceae), the lats. as bracteoles, the post. as a true sep. $C \infty$, 4 outer alt. with K, 4 inner with these; each of the 8 begins a spiral of pets., usu. 4 in each, alt. approximately with one another and the outer 8, and showing gradual transition to the 50—100 sta. which continue the spirals. K hypog., C and A inserted up sides of G (10—20)-loc. with sessile stigmas on upper surface, and ∞ ovules scattered over the whole carpellary surface (cf. Butonus). Fr. a large berry; ∞ seeds, each with spongy aril entangling air bubbles; the seeds float up on dehisc. of fr., and float about till the aril decays. Perisperm round endosp. proper. N. was the original sacred Lotus of Egypt; Nelumbium (q.v.) was introduced about 500 B.C. (Conard, The Waterlittes, Washington, 1905).

Nymphaeaceae (ÉP., BH.). Dicots. (Archichl. Ranales; pp. xvii, l). 8/50 trop. and temp. Water or marsh pl., usu. with rhiz., aerial, floating, or submerged l., and sol. usu. large fls. of great variety of pattern (described in detail under gen., q.v.). Cabomba with completely free cpls. agrees best with other Ranales, whilst great modification, espec. in G, shows in the other groups. Nelumbium is still apocp., though cpls. connected by torus. The rest are syncp., sup. in Nuphar, semi-inf. in Nymphaea, inf. in Victoria. Much variety in P (cf. Cabomba and Nuphar); K often 4; A usu. ∞ (6—∞); G to G 3—∞, free or united, each with r—∞ anatr. ov. on inner surface. Fr. berry-like; seed with endosp. and perisperm, or none, often arillate. (Cf. Eichler, Blutendiagr., Arber, Water Plants, Conard,

Classification and genera. [The Waterlilies.]

011 occurs in plants in two forms, the fixed oils, or non-nitrogenous reserves in seeds, and the volatile oils, which give the perfume to many fls. and 1. The former are obtained by pressure, the latter by distillation. Fixed oils from Aleurites, Arachis (groundnut), Argania,

Barringtonia, Brassica (rape, colza), Calophyllum, Carya, Cocos (coconut), Corylus, Croton, Elaeis (palm oil), Eruca, Fagus, Ginkgo, Glycine (soja, soy), Gossypium (cottonseed), Guizotia (nigerseed), Helianthus, Juglans (walnut), Linum (linseed), Melia, Moringa. Olea (olive), Papaver, Polygala, Ricinus (castor), Sapium, Schleichera, Sesamum (gingelly), Theobroma (cacao-butter), Tilia, Vateria, &c., &c. Some of these are drying oils, like linseed, and used in painting, some remain fluid, some are solid or fatty, esp. in Europe. More solid fatty bodies are obtained from Bassia, Butyrospermum, Caryocar, Pentadesma, &c. Volatile oils from Acacia, Backhousia, Calamintha, Cananga, Cinnamomum (cinnamon), Citrus (lemon, &c.), Cymbopogon (citronella, geranium, lemongrass), Dictamnus, Eucalyptus, Eugenia (clove), Gaultheria (wintergreen), Jasminum, Labiatae, Lavandula (lavender), Lippia, Melaleuca, Mentha (peppermint), Nardostachys (spikenard), Origanum, Pelargonium, Pogostemon (patchouli), Reseda, Rosa, Rosemarinus, Santalum (sandalwood), Sassafras, Thymus, Viola, &c., &c.

Ola (Ceylon), Borassus, Corypha, &c.

Olacaceae (EP.; Olacineae p. p. BH.). Dicots. (Archichl. Santalales). 25 gen., 120 sp., trop. Most are shrubs or trees with alt. entire l. and small 7 reg. fls. There is a distinct K, resembling the calyculus of Loranthaceae, but probably not equivalent to it. C 4—6; A as

many or 2 or 3 times as many; G partly sunk in the disc, or free, 2—5-loc. at base, 1-loc. above, with free plac. and 1 ovule hanging down into each loc. (occasionally 1-loc. 1-ovuled). Drupe or nut, one-seeded. Seed with testa and endosp. Chief genera: Ximenia, Olax.

Olacales (BH.). The 8th order of Polypetalae.

Olacineae (BH., Olacaceae + Icacinaceae EP.). Trees and shrubs with usu. alt. 1. and axillary infl. of \(\frac{1}{2} \) or unisexual reg. fls. K, C (4-5-6), A 4-10, rarely 12, \(\frac{G}{2} \) free or partly in disc, (3-5), 1- or multi-loc. with few ovules. Drupe 1-seeded. Endosp.

Olax L. Olacaceae. 35 palaeotrop.

Oldenburgia Less. Compositae (12). 3 Cape Colony.

Oldenlandia L. (ıncl. *Hedyotis* L.). Rubiaceae (1. 2). 180 warm. Some are heterostyled (dimorphic).

Oldfieldia Hook. Euphorbiaceae (A. I. 1). I trop. W. Afr., O. africana Benth. et Hook. f., the African oak. Good timber.

Old maid (W.I.), Vinca rosea L.; -man, Artemisia Abrotanum L.; --'s beard, Tillandsia; -- cactus, Cereus sentis Salm-Dyck; -woman's bitter (W.I.), Picramnia; -witch grass (Am.), Panicum capillare L.

Olea (Tourn.) L. Oleac. 35 Medit., Afr., Indomal., Austr., N.Z., Polynes. O. europaea L. (olive), cult. in Medit. region from early ages. The wild form has thorny twigs and a small fr., the cult. form (var. sativa DC.) is smooth and has a large drupe with oily flesh. The oil is obtained by bruising and pressing the fruit. Several yield good timber, e.g. the olive, O. laurifolia Lem. (S. Afr.; black ironwood), &c.

Oleaceae (\$\bar{E}P\$, \$BH\$). Dicots. (Sympet. Contortae; Gentianales \$BH\$). 21 gen., 400 sp., trop. and warm temp., esp. E. Ind. Shrubs and trees usu. with opp. 1., which are exstip., simple or pinnate, often entire. Serial accessory buds occur in the leaf-axils of many sp. (e.g. Syringa) in both fig. and veg. parts. The infl. is racemose or cymose, often bracteolate. Fls. \$\frac{1}{2}\$, rarely unisexual, reg., 2—6-merous, sometimes poly- or a-petalous (Fraxinus, &c.). K typically (4), valvate; C (4) valvate or imbr., rarely conv.; A 2, epipet. usu. transv. placed, and alt. with cpls.; no disc; \$\frac{1}{2}\$ (2); stigma 2-lobed on simple style; ov. 2-loc. with 2 anatr. ov. in each loc. Berry, drupe, or caps., or schizocarp, with 1—4 seeds. Endosp. or none, embryo straight. Olea, Fraxinus, &c., are of economic value.

Oleander, Nerium Oleander L.

Oleandra Cav. Polypodiaceae. 10 trop.

Olearia Moench. Compositae (3). 90 Austr., N.Z., New Guinea. Replaces Aster, and closely resembles it, but all trees or shrubs.

Oleaster, Elaeagnus, Olea.
Oleiferus (Lat.), oil-bearing.

Oleine, Cocos.

Oleoxylon Roxb. Dipterocarpaceae. 1 Burma.

Oleraceus (Lat.), esculent.

Orchidaceae (EP., BH.). Monocots. (Microspermae). 450 gen., 7500 sp., cosmop., abundant in trop., rare in arctic regions. They agree in some general features of habit, &c., e.g. they are all perennial herbs, but differ widely in detail, owing to the diversity of conditions in which they exist—land-plants, epiphytes, saprophytes, &c. Within the trop, they form an important feature of the veg., living chiefly as

epiphytes. Most temp. zone forms are terrestrial.

The plant as a whole may be built up in one of three ways. (1) a monopodium, the main axis growing steadily on, year after year, and bearing the fls. on lat. branches; (2) an acranthous sympodium, the main axis being composed of annual portions of successive axes, each of which begins with scale 1. and ends in an infl.; (3) a pleuranthous sympodium, where the infls. are borne on lateral axes, the shoot which for the current year continues the main axis stopping short at the end of its growing period, and not ending in an infl. These types of construction are used in classification (see below).

The saprophytes are few; they have no green l.; below the soil, in the humus, is a fleshy rhiz., with (Neottia) or without roots. It is much branched, and does part or all of the work of absorption. Mycorhiza occurs in most or all. The terrestrial forms are all sympodial, and have usu. a rhiz.; each annual shoot bends up into the leafy shoot of the current year. Many being xero., and all perenn., it becomes a necessity that there should be a storage reservoir to last over the non-veg. period of the year. In a great many this takes the form of a thickened internode of the stem: in many again, among which the Brit. orchids are included, the bud for the next year's growth, i.e. the next part of the sympodium, is laid down at the base of the stem, and from it is developed a thick and fleshy adv. root, forming a large tuber, which lasts over the winter.

Coming lastly to the epiphytes, abundant in the trop., we find great variety. [See Schimper, Die epiphytische Vegetation Amerikas.] They are mostly sympodial, but the few monopodial O. also belong to this group. The exceedingly light seeds and the xero habit of many O. fit them to become epiph. The roots of the epiph. forms are of interest. In the first place, to fasten the pl. to its support there are 'clinging' roots, insensitive to gravity, but negatively heliotropic. The niche between the pl. and its support and the network formed by the roots act as reservoirs for humus, and into this project 'absorbing' roots, branches from the others; these are usu., Schimper asserts, negatively geotropic. Finally the true aerial roots hang down in long festoons. The outer layers of cells (the epidermis and velamen) are dead and perforated, and act as a sponge to absorb water trickling over them. Their internal tissue is green (as may be seen on wetting a root) and assimilates. During the dry season a great proportion of the O. drop their l. (though they may flower), and 'hibernate' in the condition of fleshy pseudobulbs. One pseudobulb, which is a thickened stem-internode, is usu. formed each year. In this, water and other reserves are stored. Those epiphytes which do not form these tubers have fleshy l. which serve the same end; the fleshy leaved orchids, s.g. Vanilla, have usu. a very feebly developed velamen. Some monopodial forms have no green l. at all, assimilating either by the surface of the stem, or by the long dangling aerial roots (Polyrrhiza, &c.).

The infis. are racemose, very often spikes, which look like racemes, the long inf. ovary resembling a stalk. The fi. is 1- and departs from the ordinary Monocot. type. There are two chief divisions of O., with different fis., the *Monandrae* and *Pleonandrae*, with 1 and 2 starespectively; the great majority are monandrous. P in 2 whorls,

epig., petaloid. The post, petal is usu, larger than the rest, and is termed the labellum; by the twisting (resupination) of the ovary through 180° it comes round to the ant. side of the fl. and forms a landing place for insects. In many O. its structure is exceedingly complex. essential organs of the fl. are all comprised in a central structure by which the O. can be recognised at a glance, viz. the column, which consists in the simpler cases of the combined style and sta. (to use the old-fashioned expression: in reality it is very probably an outgrowth of the axis, bearing the anthers and stigmas at the top). In the monandrous forms the column exhibits one anther and two fertile stigmas (often ± confluent), together with a special organ, the

Floral diagram of Orchis, before resupination (after Eichler, modified); LAB = labellum, STD=staminode.

rostellum, which represe the third stigma. The single anther is the ant. one of the outer whorl (if we imagine the fl. of O. derived from a typical 3-merous fl.); the other two of this whorl are entirely absent, and also all those of the inner whorl, though in some genera, e.g. Orchis, the ant. two are represe by stds. upon the sides of the column. The two fertile stigmas are the post. pair, and the third (ant.) is represe by the rostellum (in using the terms ant. and post., the resupination is supposed not to have occurred).

The various organs face the labellum, and, in the fl. of a simple O., e.g. Orchis, can easily be made out. A little above the base are the two stigmas, then above these a projecting point, the rostellum, and above this again, and behind it, forming the apex of the column, is the anther, which shows two lobes. Each is occupied by a pollinium, or mass of pollen. Under the microscope the grains of pollen are seen to be tied together in packets by elastic threads; these unite at the base of the pollinium and form a cord, the caudicle, which runs

down into, and is attached to part of the rostellum.

The simple construction found in Orchis, &c., as thus described, is replaced by much more complex arrangements in many. The labellum itself may be rendered very complex, by the addition of spurs and other outgrowths; often outgrowths of the summit of the receptacle take place, displacing some of the organs, thus for example

in Drymoda and others, the labellum and the sepals on either side of it are carried forward on an axial protuberance in such a way that the sepals appear to spring from the labellum, the axial growth (chin) appearing like the basal part of this organ. Some of these constructions are very complex. Several are described in connection with the genera to which they belong.

Similarly the column shows great variety in structure (refer as above). One point may be mentioned specially as of importance in classification. In the simple case of Orchis, &c., described above, the base of the anther loculi is against the rostellum; such cases are called basilonic; in others it is the apex that is next the rostellum (Oncidium.

&c.), and these are acrotonic.

[Diandrae. So far only monandrous forms have been considered. In Cypripedium and its allies the column has 2 anthers, no rostellum, and a simple stigma, composed of the 3 carpellary stigmas. The two sta. belong to the inner whorl, and the sta. which in Monandrae is fertile, is here repres. by a large std. The stigma is not sticky, but the pollen is, and it is not combined into pollinia.]

The ovary is inf. in all O., uniloc. with 3 parietal plac. (exc. Apostasia), and ∞ ovules, which do not develope until fert. of the fl.

occurs.

The adaptations of orchid flowers to fertilisation by insects are endless, and many very complicated. Reference must be made to text-books for the details. No student should omit to read Darwin's Fertilisation of Orchids, at least the first two and the last chapters. In it will be found accounts of the mech. of most of the common gen. A few general points only can be mentioned here; in the description of the individual gen. other details are given. Very few secrete free honey; in most cases the insect has to bite into or drill the tissue for the juice therein contained; this tissue is usu. part of the labellum often a spur at the base—or the basal part of the column. The pollinia are removed as a rule when the insect is going out of the fl. In most cases the insect in entering displaces the rostellum or some portion of it, and thereby exposes and comes into contact with a sticky mass (due to disorganisation of cells formerly living). becomes cemented to the insect while it is drilling for honey, and as the insect goes out again it takes with it the viscid lump, together with the pollinia, either merely glued to it, or attached by caudicles. In many cases the pollinia are in such a position that when the insect enters the next fl. they will touch the stigmas. In others this is not so, e.g. Orchis, where the anthers and stigma are far apart on the column, and in such cases the pollinia, on getting out of the anther, execute a hygroscopic movement which brings them into the proper position on the insect's body to strike the stigmas. Such is the general principle of the orchid mechanism, but the variety in detail is endless. Many fis, have the most extraordinary structure, e.g. Coryanthes, Stanhopes, Vanda, &c. See under gen.

The fruit is a cags., containing usu. a gigantic number of exceedingly small and light seeds; which are well suited to wind distr.

(hence, among other causes, the epiph. habit of so many).

The O. are favourites in horticulture, and very many gen. are cult.

There are many generic hybrids; the names of most of those as yet produced, e.g. Orchicoeloglossum, Phaiocalanthe, Zygocolax, are included in this book. Vanilla is the only orchid of economic importance.

Classification and chief genera (after Pfitzer):

I. PLEONANDRAE (two stamens).

1. Apostasieae: Apostasia.

2. Cypripedileae: Cypripedium.
II. MONANDRAE (one stamen).

a. Basitonae (basitonic, anther not falling off):

. Ophrydeae: Ophrys, Orchis, Habenaria, Disa.

b. Acrotonae (acrotonic, anther usually falling easily):

a. ACRANTHAE (acranthous sympodial):

I. Convolutae (I. convolute in bud, with no distinction between blade and sheath):

. Neottieae: Vanilla, Epipactis, Neottia.

II. Articulatae (as I., but with a joint between blade and sheath):

3. Coelogyneae: Coelogyne, Pholidota. III. Duplicatae (l. folded in bud):

4. Liparideae: Liparis, Corallorhiza.

5. Polystachyeae: Galeandra.

6. Laelieae: Epidendrum, Cattleya, Laelia.

7. Sobralieae: Sobralia.

Orchis (Tourn.) L. (BH. incl. Anacamptis Rich., Himantoglossum Spreng.). Orchidaceae (II. 1). 70 Eur., temp. As., N. Afr., Am.

(10 Brit., incl. O. mascula L., early purple orchis, and O. maculata L., spotted orchis.) Sympodial perennials forming one tuber each year (see fam.). The fls. stand in a dense spike and have curious mech, for insect fert. The anther is basitonic and well above the stigmas. The rostellum has an outer firm pouch, inside which is the viscid substance to which are firmly attached the caudicles of the pollinia. An insect entering the fl. probes the spur of the labellum and its back comes into contact with the rostellum and depresses the pouch, causing the viscid substance to adhere to the insect. tissue of the spur has to be drilled for honey, and while this is being done the cement rapidly sets, so that, as the insect leaves the fl., it takes with it the pollinia, standing upright on their caudicles. If they remained in this position they would never touch the stigmas of another fl., but as soon as the caudicles are exposed to air, they contract on the side towards the base of the fl. (i.e. towards the insect's head) and move the pollinia downwards from ! to -. In this position, when the insect enters another fl., they pass under the rostellum and strike the stigmas. [See Darwin's Orchids for details.]

Orchis, Orchis, any terrestrial member of Orchidaceae; bee-, Ophrys apifera Huds.; bird's nest-, Neottia; butterfly-, Habenaria, Oncidium; dove-, Peristeria; early purple-, Orchis mascula L.; fly-, Ophrys muscifera Huds.; frog-, Habenaria (Coeloglossum) viridis R. Br.; lady's slipper-, Cypripedium; man-, Aceras anthropophora R. Br.; musk-, Herminium Monorchis R. Br.; scented-, Gymnadenia conopsea R. Br.; spider-, Ophrys aranifera Huds.; spotted-, Orchis maculata L.

A.D. Orchis mascula (Purple Orchis). A. Front view of anther and top of column; a, anther; s, s, pair of stigmatic surfaces, one on each side of the rostellum, r. The pollen-sacs have split lengthwise, exposing the pollinia in the upper portion. On either side of the anther is a blunt outgrowth representing a sterile stamen. B. Dissection of flower, side view, showing part of lip and the spur (s) and the relation of rostellum (r) and stigma (s) to entrance of spur. C. Base of pair of pollinia, front view; c, caudicles; r, rostellum; g, gland; m, membranous disc. D. Single pollinium, the pollen-containing portion separated, showing arrangement of packets of pollen on the two main axes.

E. Pollinia of O. pyramidalis attached to a common gland (g).

All enlarged. A, D, from original drawing by Fr. Bauer B, C, E, after Darwin.

Ornamental plants, whether cult. for fl., fr. or l., or as ornamental shrubs or tiees, are very numerous, and cannot be listed. Against most important genera thus employed are placed such notes as "cult. orn. fl." So far as the cold zones are concerned they may be roughly classified into hardy pl., which will stand the winter out of doors, half-hardy, which require protection during winter, or if annual to be germinated under glass and planted out, cool house plants from warmer climates than England, succulent house plants from dry climates, and stove plants from hot moist trop. climates. Or in another way, they may be grouped into ornamental trees, shrubs, and herbs, with the minor groups of water-plants, climbers, &c.

Ouvirandra Thou. = Aponogeton Thunb. (Apon.).

Oval (1.), widish, tapering equally to base and tip.

Ovary, the hollow chamber formed by the infolded sporophylls, in which the ovules are borne on thickened placentae or cushions. It may be superior (on apex of torus above sta.) or inferior (sunk in torus below sta.) or intermediate, apocarpous (free cpls.) or syncarpous (united), in spirals or whorled, radial or + in symmetry. It may be unilocular (1-chambered), or bi- tri- locular, &c. (often simply called multiloc.). The imaginary joins of the cpls, are called the sutures (ventral if at the centre), and the midrib of the cpl. is called the dorsal suture. The placenta may bear one, two or more rows of ovules, or one or two ovules only. The partitions of the ovary are called the septa, and false septa, chambering it into more loc. than normal, are found in Astrogalus, Cruciferae, Gaylussacia, Linum, &c.

DIAGRAMMATIC LONGITUDINAL SECTIONS OF FLOWERS, to show types of receptacle, ovary, stigma, sec. A, hypogy nous flower with unilocular ovary, parietal placentation, and numerous ascending anarropous ovules with raphe downwards; stigma sessile, bilobed. B, perigynous flower with multi-locular ovary, axile placentation, and numerous horizontal anatropous ovules with raphe upwards; style with bifid stigma. C, epigynous flower with multi locular ovary, apical placentation, and solitary pendulous anatropous ovules with ventral raphe; style long with capitate stigma. r, receptacle; h, calyx; c, corolla; a, stainens; o, ovary; st, stigma.

The style, if present, may be long or short, cylindrical, filiform, ribbed, &c.; it may be terminal, lateral, or basal. The stigma or stigmas may be sessile or on a style, simple (and then often capitate or head-like), lobed, fid, radiate, &c.

The ovule may be sessile or stalked (on a funicle); erect, ascending,

horizontal, or pendulous. It may be ortho- or atropous (in a line with stalk, micropyle away from the latter), anatropous (reversed, and attached to stalk along side), amphitropous (stalk attached to middle of ovule), or campylotropous (ovule itself curved into U shape).

Ovate (l.), about twice as long as broad, tapering to the tip.

Overlook (W.I.), Canavalia ensiformis DC.

Ovidia Meissn. Thymelaeaceae. 4 Chili. Ovieda L. = Clerodendron L. (Verben.).

Ovoid, solid oval.

Ovule, the possible future seed, of. Ovary.

Ovuliferous scale, cf. Coniferae.

Ovum, the ? sexual cell, Angiospermae, Pteridophyta. Owataria Matsumura. Guttiferae (v). 1 Formosa.

Owenia F. Muell. Meliaceae (III). 5 Austr.

Oxalidaceae (EP.; Geraniaceae p.p. BH.). Dicots. (Archichl. Geraniales). 7 gen., 850 sp., mostly trop. and subtrop. Most are perennial herbs with alt. often cpd. exstip. l. and large fls., usu. in cymes, y, reg. K 5, imbr., persistent; C 5, twisted or imbr., free or slightly united; A 10, obdiplost. (i.e. the outer whorl opp. to the petals, the inner to the sepals, and thus the cpls. opp. to the petals, instead of to the sepals, as in diplostemonous fls. with two whorls of sta. in proper alternation), united below, with introrse anthers; G (5), with free styles, 5-loc., with axile plac.; ovules in 1 or 2 rows in each loc., or few, anatr., with micropyle facing upwards and outwards. Capsule or berry; embryo straight, in fleshy endosp. Chief genera: Oxalis, Biophytum, Averrhoa. Closely allied to Geraniaceae. The chief difference is in the fruit.

Oxalis L. Oxalidaceae. 800 cosmop. chiefly S. Afr., Am. O. Acetosella L. (wood-sorrel) in Brit. is a small herb with monopodial rhiz,
and ternate l., which sleep at night and in cold weather, the leaflets
bending downwards. The fl. is protandr.; the stalk bends downwards and the fl. closes in dull or cold weather. Cleistogamic fls.
(cf. Viola) occur. Loculic. caps. The seed has a fleshy aril springing
from the base. When ripe the cells of the inner layers are extremely
turgid, and a small disturbance causes the aril to turn inside out, as
one might turn a glove-finger, from U to \(\Omega\$. This is done instantaneously and the seed is shot off.

Many have bulbous or tuberous stems. Some, e.g. O. bupleurifolia A. St Hil., have phyllodes in place of the ordinary I. (cf. Acacia). Fls. sol. or in cymose infls. Many exhibit trimorphic heterostyled fls. (see Darwin, Forms of Fls.); there are three stocks of pl., one bearing fls. with long styles, and mid- and short-length sta., the others with mid or short styles and correspondingly long and short or long and mid sta. (cf. Lythrum). Some produce axiliary bulbils; others repr. veg. by underground offshoots. The tubers of O. Deppei Lodd. (S. Am., Mex.), and others, are used as food.

Oxandra A. Rich. (Bocagea p.p. BH.). Anonaceae (1). 7 trop. Am.

Wood useful.

Oxera Labill. Verbenaceae (4). 15 New Caled.

Oxeye-daisy, Chrysanthemum Leucanthemum L.; oxlip, Primula elatior Hill.

Palmae (EP., BH.). Monocots. (Principes; Calycinae BH.). 200 gen., 1500 sp. trop. and subtrop.; most of the gen. well localised in the various floral regions, the chief exceptions being Cocos nucifera, Elacis guineensis and Raphia vinifera. The palms form a char. feature of trop. veg. The veg. habit is familiar-a crown of l. at the end of an unbranched stem (Hyphaene is branched). The stem exhibits various forms; some palms, e.g. Nipa, Phytelephas, have a short rhiz. or stock bearing 'radical' leaves and often branching below ground; some, e.g. Geonoma, Calamus, Desmoncus, have a thin reed-like stem with long internodes (the two latter are climbers); others again have a tall stem with a crown of 1. at the top. The stem is often covered with the remains of old leaf-sheaths, or is thorny. Its height may reach 150 feet in some, and it grows slowly in thickness. At the base the stem is usu. conically thickened or provided with buttress roots; this gives the necessary mechanical rigidity. The stems of Cocos and other palms are curved instead of straight; this appears to be due to reaction to light.

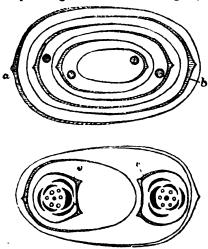

The l. is very characteristic; the only closely similar l. is that of Carludovica, though those of Cycads and some tree ferns have a superficial likeness. Some have palmate (fan) 1., some pinnate (feather) 1., but this structure arises by a development unlike that which gives rise to these forms in Dicots, and more like that in Araceae. The l. is usu. very large, and at the base of the petiole is a sheath, which makes a firmer attachment to the stem than a mere articulation. The sheath contains many bundles of fibres, which remain after the decay of the softer tissues. The pinnae are folded where they meet the main stalk of the 1., sometimes upwards (induplicate, V in section), sometimes downwards (reduplicate, A in section); these chars, are important in classification. The l. emerges from the bud in an almost vertical line and thus escapes excessive radiation and transpiration. The palms are pronounced sun-plants, and show xero. chars. in their l. surface is glossy with a thick cuticle, and is rarely arranged 1 to the incident rays. Often the l. is corrugated, or placed at an angle by the twisting or upward slope of the stalk; sometimes the leaflets slope upwards, and so on.

Infl. usu. very large and much branched. In Corypha and others it is term, its production being a mark of the end of the life of the plant (cf. Agave), but usu. it is axillary; sometimes in the axils of the current l., sometimes lower on the stem. The branching is racemose and the fls. are often embedded in the axis; the whole is often termed a spadix. It is enclosed in a spathe of several l. and emerges when the fls. are ready to open. Some are diœc., some monœc., in the latter case often with the fls. in groups (small dichasia) of 3, one? between two d.

The fl. has usu. the formula P 3+3, A 3+3, Q 3 or (3). Phomochiam., varying in texture. G (3) 1-loc. or 3-loc., with 3 or sometimes 1, anatr. ovules (rarely semi-anatr., or orthotr.). Some are wind-pollinated, others are entomoph.

Fr. a berry or drupe; in the latter case the endocarp usu. united to the seed. Fr. in § 111 covered with dry woody scales. Endosperm large; in date, vegetable ivory, &c., it is very hard, the non-nitro-

genous storage-material taking the form of cellulose, deposited upon the cell walls. In germ, the cot, lengthens and pushes out the radicle, and then the plumule grows out of the sheathing cotyledon.

Diagrams of Raphia (after Euchler). Above, the arrangement of the last branches of infl. a, b, two of the sterile sheathing bracts, above them bracts with branches in their axils, a little out of the median line. Below, arrangement of the flowers on branches of upper figure: bracts 2-ranked; each fi has a 2-keeled bracteole v.

Economically, the P. are very important, furnishing many of the necessaries of life in the tropics, &c. Many have ed. fr. or seed, e.g. date (Phoenix) and coco-nut (Cocos); the stems contain much starch as reserve food, esp. in those sp. which save up for a great terminal infl., e.g. Metroxylon (sago), Caryota, &c.; the rush of sap to the infl., esp. in the cases just mentioned, is great; and by tapping the stem great quantities of sugar-containing fluid may be obtained and utilised, either directly as a source of sugar or indirectly to make intoxicating drinks by fermentation. The bud of l. at the top of the stem is sometimes used as cabbage, but of course its removal kills the tree. The stems are used in building, but do not yield plank-timber; the I. in thatching and basket-making, and for hats, mats, &c.; the fibres of the leaf-sheaths or sometimes of the pericarp (e.g. Cocos) are used for ropes, &c.; other P. furnish oil from the seed (a.g. Elaeis, Cocos), wax (Copernicia), vegetable ivory (Phytelephas, &c.), betel-nuts (Areca), &c. [Cf. Baillon, Hist. des Pl. X111. 183.]

Classification and chief genera (after Drude):

A. Perianth 6-partite, enclosing the fruit after fertilisation.

 CORYPHOIDEAE (spadix loosely branched, often a prolix panicle; fis. single or in long rows flowering from above; cpls. 3, or loosely united, separating after fert.; berry; fan or feather I., induplicate):

1. Phoeniceae (feather l.): Phoenix.

2. Sabaleae (fan l.): Chamaerops, Rhapis, Corypha, Livistona, Sabal, Copernicia.

II. BORASSOIDEAE (spadix simple or little branched with thick cylindrical twigs; fls. markedly diclinous dimorphic, invested with bracts, the & in 1-∞ cincinni in grooves of the twigs; cpls. (3), fully united, producing a one-seeded drupe; fan l., induplicate):

Borasseae: Hyphaene, Borassus, Lodoicea.

III. LEPIDOCAR YOIDEAE (spadix branched once or more in a 2-ranked arrangement; fls. in cincinni or 2-ranked spikes with bracts and bracteoles round them; cpls. (3), fast united, covered with scales; fr. 1-seeded, covered with hard scales; feather or fan l., reduplicate):

.. Mauritieae (fan l.): Mauritia.

2. Metroxyleae (feather I.): Raphia, Metroxylon, Calamus. IV. CEROXYLOIDEAE (spadix simple or one or several times branched; fls. diclinous, usu. dimorphic; when dioec. sol. with rudimentary bracts, when monoec. usu. in cymes of 3 fls., 2 being 3 and 1 2, or rarely of and 1 at the end of the row being ?; cpls. (3), 3- 2- 1-loc.; fruit smooth, not scaly; feather l.):

1. Areceae (berry fr.): Caryota, Arenga, Leopoldinia, Iriartea, Ceroxylon, Chamaedorea, Oreodoxa, Euterpe, Kentia, Areca.

Cococae (drupe fr.): Elaeis, Attalea, Cocos, Bactris, Desmoncus.

B. Perianth rudimentary in d or ?. Fruit in dense heads.

PHYTELEPHANTOIDEAE (3 fl. with ∞ free sta.: with P; endosp. ivory-like): Phytelephas (only gen.). NIPOIDEAE (& with (3) sta.; ? naked; woody endo-

carp): Nipa (only gen.).

For further details of P. see Nat. Pfl., Seemann's History of the Palms. and Treas. of But.

Palmate, divided, and arranged like the leaves of a fan.

Palmatifid, -partite, -sect, palmately divided to 1-1, 1-2, over 2 of the depth.

Pandaoeae (EP.). Dicots. (Archichl. Pandales). Only gen. Panda, q.v. Pandales. The 22nd. order of Dicots. Archichl. Only fam. Pandaceae. Pandanaceae (EP., BH.). Monocots. (Pandanales; Nudiflorae BH.).

3 gen., 225 sp., char. pl. of the Old World tropics, but a few warm temp. Mostly sea-coast or marsh pl. with tall stems supported upon aerial roots, frequently branched; buds are found in all axils, and the branching appears dichotomous; some are climbers. The aerial roots have marked root-caps of membranous texture. L. in 3-ranked phyllotaxy, but stem usu. twisted so that they appear to run in well-marked spirals, whence the name of screw-pines. L. parallel-veined, long, and narrow, with open sheath and usu. thorny margin; generally sharply bent downwards at the middle, and corrugated like a palm l.

Infl. term., with a few bract-like l. at the base going gradually over into the foliage l., usu. a racemose spadix with neither bracts nor bracteoles to the individual fls., which are somewhat difficult to make out. The & fls. in sp. of Freycinetia have a rudimentary G, but in the rest of the fam. they have not. The floral axis of the & fl. bears a number of sta., arranged in a raceme or umbel-like manner upon it. The G in the & fl. of & cpls. in a ring, 1-loc. or & -loc., the union being \(\pm\) complete, or it may be reduced, even to 1 cpl., or to a row of cpls. arranged transv. Stigmas sessile. Ovules anatr. Berry or multi-loc. drupe, often containing hollow spaces which aid it in swimming. Seed with oily endosp. The plants yield thatch, &c. Genera: Sararanga (infl. paniculate; fls. pedicelled; drupe), Freycinetia (infl. capitulate or spicate; fls. sessile; berry), Pandanus (infl. as last; fls. sessile; drupe).

Pandanales. The 1st order of Monocots. Cf. p. ii.

Pandaneae (BH.) = Pandanaceae.

Pandanophyllum Hassk. = Mapania Aubl. p.p. (Cyper.).

Pandanus Rumph. ex L. f. Pandanaceae. 180 palaeotrop. (screw-pines). Trees with flying-buttress roots. Fls. in large heads, enclosed in spathes. ♂ of ∞ sta., arranged in various ways upon the axis, ? of 1.—∞ cpls., free or united. Each gives a drupe containing as many

seeds as cpls. Seeds album. The pericarp is rich in fibres. The fr. of some are cooked and eaten, s.g. P. leram Jones, the Nicobar breadfruit. The l. of many are used for weaving, s.g. P. tectorius Sol., which is cult. in Java. Several have sweetly scented fis. or l. which are used for ornament and otherwise in the East.

Panderia Fisch. et Mey. Chenopodiaceae (A). 1 Syria, Persia.

Pantlingia Prain (Stigmatodactylus p.p. EP.). Orchid. (II. 2). I Himal.

Panurea Spruce ex B. et H. f. Leguminosae (III. 1). I N. Brazil.

Papain, papaw, Carica Papaya L.

Papaver Tourn. ex L. Papaveraceae (II). 110 Eur., As., Am., S. Afr., Austr. P. Rhotas L. and 3 others (poppy) in Brit. The fls. nod in bud, not by their own weight, but by more rapid growth of one side of the stalk. Ovary crowned by a sessile rayed stigma, each lobe of which stands over a placenta instead of as usual over a midrib. This is commonly explained by supposing each actual ray of the stigma to be formed of one half of each of two adjacent stigmas. The fl. of most contains no honey, and is homogamous; both cross- and self-pollination usually occur with insect visits. Fr. a round caps., opening by pores under the eaves of the roof formed by the dry stigmas, so that the seeds are protected from rain and can only escape when the capsule is shaken by strong winds or other agencies (censer mechanism, f.

Aconitum). P. sommiferum L. is the epium poppy; the drug is obtained by cutting notches in the half ripened capsules, from which the latex exudes and hardens. The seeds of this and other sp. yield an oil on pressure.

Papaveraceae (EP., BH.). Dicots. (Archichl. Rhoeadales; Parietales

BH.). 28 gen., 600 sp., chiefly N. temp. Most are herbs with alt. l., and §§ I. and II. contain latex. Corydalis and Fumaria are climbers, Bocconia a shrub. Fls. sol. or in racemes, or in dichasia with cincinnal tendency, reg. or irreg., y, hypog. (exc. Eschscholtzia). K a (united in Eschscholtzia), caducous; C 2+2, volled or crumpled in bud (see Hypecoum); A 4 or ∞ or 2 (see sub-fams.); in the last case each sta. branches into 3 parts (see fig.), the centre one bearing an entire anther, the lat. ones each half an anther; G (2-0), 1-loc. with parietal plac., which in Papaver, &c. project into the loc.

Floral diagram of Corydalis cava (after Eichler)

Ovules generally ∞ , anatr. or slightly campylotr. Fr. a septic. caps., or one opening by pores, or a nut; seeds with oily endosp., and small embryo. The fls. are mostly large and conspicuous, but many contain no honey and are visited by pollen-seeking insects; they are often protandr. Those of sub-fam. III. are irreg., and adapted to bees in a way somewhat like that found in Leguminosae. The order is of little economic value; see Papaver.

Classification and chief genera:

I. HYPECOIDEAE (petals without spur; sta. 4; cpls. 2):
Hypecoum.

PAPAVEROIDEAE (as I., but sta. ∞; cpls. 2-∞):
 Eschscholtzia, Chelidonium, Glaucium, Papaver.

III. FUMARIOIDEAE (petals with spur; sta. 2, each branched into 3): Dicentra, Corydalis, Fumaria.

Many authors split off III. as a separate fam., Fumariaceae.

Papaya Tourn. ex L. = Carica L. (Caric.).

Papayaceae = Caricaceae.

Paper is made from fine fibre that is entirely (or almost) composed of cellulose. The best is made of cotton and linen rags; and cf. Bamboo, Borassus, Broussonetia, Fatsia, Hedychium, Lepidosperma, Streblus, Zea, &c. Adansonia, Coniferae (the wood, pulped), Cochorus, Crotaloria, Musa (textilis), straw, &c. are also used.

Passiflora L. (BH. excl. Tacsonia Juss.). Passifloraceae. 400 chiefly Am.; a few in As. and Austr., 1 in Madag. Climbing pl. with axillary tendrils. Some have curious bilobed I. (crescentic or swallowtailed in shape), the centre lobe not developing. At the base of the leaf-stalk there are usu. extra-floral nectaries. The fls. spring from the same axils as the tendrils, sol. or in small cymes; the bract is usu. 'adnate' to the peduncle. The recept, is hollowed into a cup, bearing on its margin 5 sepals, 5 petals, and a number of effigurations of the axis—thread-like petaloid bodies, forming a dense mass (the corona) round the central androphore, at whose apex is borne the ovary. Five sta, spring from the androphore at the base of the ovary, and are bent downwards at first; afterwards the styles bend down also. Honey is secreted at the base of the androphore. Fr. a berry; seed enveloped in a fleshy aril. Many passion-flowers cult. orn. fl. Several have ed. fr., e.g. P. quadrangularis L., the Granadilla (trop. Am.), P. maliformis L., the sweet calabash (W. Ind.), P. laurifolia L., the waterlemon. P. edulis Sims (passion fruit), &c.

Passifioraceae (EP.; BH. incl. Achariaceae, Caricaceae, Malesherbiaceae). Dicots. (Archichl. Parietales; Passiflorales BH.). 12 gen., 580 sp. trop. and warm temp. Shrubs and herbs, mostly climbers with axillary tendrils, and with alt. stip. I. Fls. v or unisexual, reg. Recept, of various shapes, often hollowed and frequently with a central andro- or gyno-phore; usu. term. by outgrowths, often of petaloid or staminodial appearance, forming the corona. K 3-5; C 3-5 or o; A 3-5; G (3), 1-loc. with parietal plac. and several or ∞ anatr. ov.; style 1, simple or branched, or 3-5 separate styles. Caps. or berry. Seed with fleshy aril and endosp. Chief genera: Modecca, Passiflora. [BH. chars. incl. those of fams. mentioned, all somewhat rare.]

Passifiorales (BH.). The 13th order of Polypetalae.

Passion-flower, - fruit, Passiflora.

Pastinaca L. Umbelliserae (111. 6). 15 N. temp. * P. sativa L. is the parsnip, a biennial, often cult. for ed. root.

Peri- (Gr. pref.), around; -anth, see below; -carp, the fruit wall; -chylous, with aqueous tissue round the green tissue; -derm, bark; -gone, perianth; -gyny, cf. Ovary; -sperm, nutrient tissue round the embryo, derived from the nucellus, Arzoaceae, Canna, Caryophyllaceae, Nymphaeaceae, Phytolaceaceae, Piperaceae.

Periandra Mart. ex Benth. Leguminosae (111. 10). 6 Brazil.

Perlanth, the outer covering of the fl., composed of non-reproductive l., usu. divided into an outer greenish whorl, the K, and an inner, coloured, the C. Concrescence is frequent, and the petals may be aborted (only recognisable for certain when many closely related forms possess them), thus giving an apetalous fl. Fl. with perianth, chlamydeous, without, naked or achlamydeous; with one whorl, hapto- or mono-chlamydeous or 'incomplete' (apetalous if the phenomenon is due to suppression of C), with two whorls, di- or diplo-chlamydeous, of two kinds (sepals forming a calyx, and petals a corolla), heterochlamydeous.

The P (K, C) may be hypo-, peri-, or epi-gynous; of free organs (poly-phyllous, -sepalous, -petalous) or concrescent (gamo-phyllous, -sepalous, gamo- or sym-petalous); in the latter case the concrescent part or tube bears the free lobes, teeth, or segments together forming the limb. It may also be regular (actinomorphic) or irregular (sygomorphic, or asymmetrical). If it fall as the bud opens, it is caducous, just after fert., deciduous; if it remain unwithered round the fr., persistent; withered, marcescent; enlarged, as in Physalis, accrescent.

A homochlam. P may be sepaloid (looking like a K in colour and texture) or petaloid (like a C). The aestivation is described in the

terms given under Aestivation.

The sepals are commonly leafy and green, but sometimes \(\pm\) woody (some Myrtaceae, &c.), or brightly coloured (Clerodendron, some Ranunculaceae, &c.). In many epig. fis. they are much reduced, \(\epsilon\), \(\epsilon\), \(\epsilon\) in Umbelliferae and Rubiaceae. In Compositae they are frequently repress by a pappus of hair or bristles. If concrescent, the K is described by the terms given for the C. In Malvaceae, some Rosaceae (\(\epsilon\)_g\), Potentilla) and Lythraceae there is an \(\epsilon\) picalyx of apparent stipular nature (see also Dipsaceae).

The petals are usu, of some other colour than green, and of delicate texture. They may be narrowed at the base, as in wallflower, into a claw (unguiculate), fringed with hair-like teeth, as in pinks (fimbriate), bi-fid, tri-fid, &c. (cf. 1.), or divided into several long segments (laciniate); they may be spurred (with long hollow projection, as in Viola), saccate or gribbous (with projecting broad pouch), scaphoid (boat-shaped, as in Loasa), &c. The general form of the sympetalous corolla may be tubular, funnel-shaped, urceolate (urn-shaped), campanulate (bell-shaped as in Canterbury bells), rotate (wheel-shaped with little or no tube, as in Veronica), salver-shaped (ditto, but with long tubular portion, as in primrose), spurred, saccate, gibbous, ventricose (swollen out all round in the basal part); if irreg., it may be labiate or bilabiate (with two projecting lips, as in Labiatae), personate (labiate, mouth closed by projecting lobe, as in Antirrhinum, &c.), helmet-shaped, ligulate (strap-shaped, as in dandelion, &c.), &c.

The shape, texture, &c. of the individual sepals, petals, calyx-lobes.

corolla-lobes, are described as if they were leaves.

Phyllo- (Gr. pref.), -phyllous (suff.), leaf; -clade, a stem structure usu. ± flattened and serving 1. purposes, Asparagus, Baccharis, Bossiaea, Carmichaelia, Hibbertia, Lathyrus, Lemna, Muehlenbeckia, Phyllanthus, Phyllocladus, Ruscus, Semele; -de, a petiole flattened and green, taking over l.-functions, Acacia, Oxalis; -dy, change of fl. organs to l.; -me, a leaf structure; -taxy, the arrangement of the l. upon the stem. It follows definite rules, esp. in flowering-plants, though it varies within certain narrow limits. may be several at each node (in whorls), or two (usu. opposite), or one (alternate). When the stem is so short that the I., as in the primrose or dandelion, are all crowded together and spring from the level of the ground, they are said to be 'radical.' In the first two cases the l. at one node usu. stand above the gaps at the node below. In the case of alt. I. there is found to be a fairly constant angle between each I. and the next one above it, e.g. in Plantago (fig.) this angle is a of the whole circumference measured the nearest way.

This fraction | represents the phyllotaxy. ing excepted the l. will stand in 8 vertical rows. each divided from the next by 1 of the circumference. Leaf 2 will be 1, 3 will be 1, 4 will be 🕯, 5 will be 🦞, 6 will be 14, 7 will be 14, 8 will be 삯, and g will be 삮, of the circumference from leaf 1, i.e. immediately over it, and three turns of the spiral above it. Hence the rule for determining phyllotaxy: start from any I. A and draw a spiral round the stem, passing by the nearest way through

wactly above A: then the number

all consecutive i. to the l. B exactly above A; then the number of l. from A to B is the denominator, the number of turns of the spiral the numerator, of the fraction representing the phyllotaxy.

In Gramineae the phyllotaxy is \(\frac{1}{2}\), i.e. alt. on opp. sides of the stem, in Cyperaceae \(\frac{1}{2}\). Nearly all other actual arrangements are terms of the continued fraction starting from \(\frac{1}{2}\), \(\frac{1}{2}\). If we add the numerators together to make a new numerator, and treat the denominators in the same way, we get the next arrangement \(\frac{3}{2}\). This with \(\frac{1}{2}\) gives \(\frac{3}{2}\), and then \(\frac{1}{2}\) and so on. It is rare to find a stem that shows

the phyllotaxy very clearly; usually in the course of growth more or less twisting occurs (cf. Pandanaceae). The benefit of the phyllotaxy is that the leaves are spread out to occupy the available space to

advantage.

Phyllotaxies of these types give shoots of radial symmetry; there are also bilateral arrangements, esp. upon horizontal shoots. Sometimes the dorsiventrality is attained by the twisting of the leaf-stalks from the positions in which they arose, but more commonly there is a more or less two-ranked (distichous) phyllotaxy, the l. arising upon the sides of the axis, and merely having to twist at their bases to place themselves horizontally; e.g. in the yew (Taxus), lime (Tilia), Abies. Anona, Betulaceae, Pinus, Ulmus, &c.

In other plants, again, alterations of phyllotaxy occur for which no explanation can be given; e.g. in Baptisia, Eucalyptus, Nolana

ceae, Quisqualis, Solanaceae, Thelygonum, &c.

Phyllocarpus Riedel ex Endl. Leguminosae (II. 8). I Rio de Janeiro.

Phyllochlamys Bur. in DC. Moraceae (1). I Indomal.

Phyllocladus Rich. Coniferae (Taxaceae, 6; see C. for gen. char.). 6 Tasm., N.Z., Borneo (celery pine). The 'short shoots' are represented by flat green leaf-like structures—phylloclades—whose stemnature is easily recognized by their position in the axils of the scale l. on the 'long shoots.' The edges of the phylloclades also bear scales. The fls. (mon- or di-oec.) occupy the position of phylloclades. Each cpl. has one axillary erect ovule. The seed has a small basal aril. The timber is useful: the bark of P. trichomanoides D. Don is used for tanning.

Pinguicula Tourn. ex L. Lentibulariaceae. 30 N. extra-trop., Andes, Antarctic zone; 3 in Brit. (butterwort), incl. P. vulgaris L. It has a rhiz. with a rosette of rad. l. arranged in ? phyllotaxy. The l. are covered with glands, some sessile, some on stalks, secreting a sticky fluid to which small insects adhere. Rain washes them against the edge of the l., which is slightly upturned: when stimulated by the presence of proteid bodies it rolls over upon itself and encloses them, and then the sessile glands secrete a ferment, digest the prey, and absorb the products, after which the l. uniolls again. P. lusitanica L. is found on the western shores of Brit. and is one of a few sp. which have migrated thus far up the Atl. coasts (common in Portugal).

Coniferae (l'inaceae 18: see C. for gen. chars.). 100 N. temp. and on Mts. in the N. trop. Evergr., resinous trees with both long and short shoots (see Coniferae). If a tree be examined in winter the main axes will be found each with a group of buds at the end, one term., the rest lat., covered with resinous scale l. Each gives rise in spring to a 'long shoot' or shoot of unlimited growth; the term. bud continues the main axis of all, forming a year's growth before branching in a similar way again. The large branches thus form rough whorls marking each year's growth. On the stem of a long shoot no green I. are directly borne, but only scales, first the bud scales above mentioned and then others in whose axils arise the 'short shoots,' or shoots of limited growth. Each of these has a few scale l. at the base of a very short stem and ends with a or more green I. of needle shape. When there are two, their upper flat sides face one another. These needle l. exhibit xero, characters; they are thick in proportion to surface exposed, they

514 PINUS

have a very stout epidermis with a hypoderm of thick walled tissue under it, and the stomata are placed at the bottom of deep pits: the

intercellular spaces too are very small.

The fls. take the form of the familiar cones, the grouped together in spikes. Each fl., whether & or ?, occupies the position of a short shoot and is of limited growth—an axis with a few scale-l. below bearing a number of sporophylls. In the s there are many sta., each with two pollen-sacs on the under side; the pollen is loose and powdery, and each grain has two bladdery expansions of the cuticle helping it to float in the air. In the 2, the cpls. are very small, but the ovuliferous scales, which show at the outside of the cone, are very large, and each bears two ovules at its base, with the micropyles facing the axis. ? cones take 2 to 3 years before the seeds are ripe. In May of the first year, the first stage may be seen-young cones, about 1 cm. long, in the position of short shoots near the tip of the lengthening axis-The ovules are not ripe for fert. In June (the time varies from year to year according to season) pollination takes place. The & cones shed their pollen in great quantities, so that in a pine forest the air is often full of it (if it rain, the phenomenon of 'showers of sulphur' may occur). and the wind carries it about. At the same time the ovuliferous scales spread apart. If a grain fall between two of them it slips down to the micropyle of an ovule, where it becomes held by the sticky fluid then exuding. After a short time the ? cones close up again. grain is brought into contact with the nucellus by the drying up of the mucilage; it forms a short pollen-tube, and then a resting period comes on. Next year in May or June the ? cone has become a fat green body about 3 cm. long, with the ovules ready for fert.; the pollen-tubes now recommence growth and reach the ova. Then in the third year the cone is mature—a hard woody cone containing the seeds between the scales. Each seed contains an embryo with a whorl of cots., embedded in rich endosp., and has a hard testa. To the end of this is attached a thin membranous wing, derived from the ovuliferous scale. In dry weather the cone opens and the seeds are blown away. In germ, the seed is lifted up above the earth by the growing plant and the cots. remain inside the testa till the reserves are exhausted. They are green whilst in the seed, though in darkness—an exception to the rule that chlorophyll requires light for its formation. During the first year no short shoots are formed, and the seedling has green I. borne directly on the main stem.

The pines are amongst the most valuable of all plants and are cultivated on an enormous scale, chiefly for their timber, which is easily worked, and resinous products. The resin renders the timber very resistent to decay, &c. Some of the more important sp. will now be mentioned. (Cf. also under Pine.)

L. PINASTER Endl. Visible part of fruit scale more or less

pyramidal with central boss.

§ 1. Pinea (short shoot with 2 or rarely 1 needles): 20 sp. P. sylvestris L., the Scotch fir, the only Brit. sp., occurs in Eur. to 68° N., in Asia to 66° N., and as far south as Spain and Italy (alpine). The wood (yellow deal) is largely used in the arts; turpentine is obtained by tapping the tree.

The resin exudes and is distilled; the distillate is oil of turpentine, the remainder rosin. Tar and pitch are correspondingly the products of destructive distillation in closed chambers. P. Pumilio Haenke (P. montana Mill.) is a shrubby decumbent sp., Pyrenees to Caucasus. P. Pinea L. (Medit.), the stone pine, furnishes edible seeds ('pignons'). P. Laricio l'oir. (S. Eur.) is the Corsican pine. P. Pinaster Ait., the cluster pine or pinaster (Medit.), is a value ble tree. It grows well near the sea, and large areas of the Landes of S. France are planted with it. It turnishes much of the turpentine Xc. in use. P. echinata Mill. the short leaved or yellow pine is a valuable N. Am. sp. P. longipolia Roxb. (H.mal.) is tapped for resin.

§ 2. Taeda (needles 3, triangular in section): 16 sp. P. Taeda L. (loblolly or frankincense pine, southern U.S.) yields turpentine. P. palustris Mill. (P. australis Mich.) (pitch-pine, U.S.) yields timber and turpentine. Other sp., e.g. P. ponderosa Dougl. and P. rigida Mill., are also known by the

name of pitch-pine.

 STROBUS Spach. Visible part of fruit scale with terminal boss. Needles usually 5 in each short shoot. 20 sp.

§ 1. Eustrobus (cones hanging, seeds winged): P. Strobus L., the Wey mouth or white pine (East N. Am.), a timber tree; P. Lambertiana Dougl., the giant sugar pine of the W. U.S.; P. excetsa Wall., the Bhotan or blue pine (E. India)

§ 2. Cembra (cones erect or drooping, seeds not winged); P. Cembra L. the Siberian cedar (Alps, Carpathians, Ural, Siber.) has ed. seeds and valuable wood; P. flexilis James (N. Am.) &c. [For further details see Nat. Pfl., Veitch's Manual of Consferae, European pine timbers in Kew Bull. 1915, p. 265, Sargent, Manual of Timbers of N. Am., &c.]

Plantaginaceae (EP., BH.). Dicots. (Sympet. Plantaginales). 3 gen., 200 sp. cosmop. (See genera.) Annual or perennial herbs; 1. without distinction into stalk and blade, exstip. Fls. usu. in heads or spikes, inconspic., usu. §, reg., without bracteoles, wind- or partly insect-fert. K (4), diagonally placed; C usu. (4), membranous; A 4,

with very long filaments and versatile anthers containing much powdery pollen; G usu. (2), 2-loc., with 1—∞ semi-anatr. ov. on axile plac. Fr. a membranous caps., opening with a lid cut off by a peripheral dehiscence, or sometimes, a nut surrounded by the persistent calyx. Embryo straight, in fleshy endosp. Genera: Plantago, Littorella, Bougueria. See P. and L. for details. The relationships of the P. are difficult to make out. The fl. is usu. regarded as derived from a 5-merous type in the same way as that of Veronica, and most authors agree in regarding the P. as degraded forms allied to Scrophulariaceae, Labiatae, &c. The wind-pollination of the fir. is also an evidence of this.

Plantaginales. The 7th order of Sympetalae; p. xlvi.

Plantagineae. (BH.) = Plantaginaceae.

Plantago (Tourn.) L. Plantaginaceae. 200 cosmop.; 5 in Brit., good illustrations of the gen. P. major L. (greater plantain) is a perennial with a thick root and a rosette of large erect l., in whose axils arise the infls. (spikes). Fl. protog., the stigmas protruding from the bud; the sta. appear later. Wind-pollination is the rule, but insects sometimes visit them for pollen. The fruit-spikes are often given as food to cage birds. P. media L. (hoary plantain) shows similar general features, but the l. lie flat on the ground (hence it is a troublesome weed); they exhibit the 3/8 phyllotaxy (q.v.) very clearly. The fl. is more conspicuous than P. major and has a pleasant scent, and though primarily wind-pollinated, is largely visited for pollen. It is sometimes gynodioec. (cf. Labiatae). P. lanceolata L. (rib-wort plantain) has narrow erect l., and fls., also gynodioec. P. Coronopus L. (buck'shorn plantain) is xero. with hairy l., growing in sandy places. Many S. Am. sp. show marked xero. characters—dense tufting, small hairy l., often grooved on the lower surface (cf. Ericaceae), &c. P. maritima I. (the sea-side plantain) has linear fleshy l.; it is found at high levels in the Scottish Mts., though rarely in the intermediate regions.

The seeds of many swell up when wetted and become mucilaginous (cf. Linum). Those of P. Psyllium L. (Medit.) are used in silk and

cotton manufacture; they have also been used in medicine.

If the young growing infl. be vigorously shaken, when left to itself it droops and only becomes erect again after some time. The strain stretches the young cell walls beyond their limit of elasticity.

Plantain, Musa paradisiaca L. (in India &c., incl. Musa Sapientum L., the banana), Plantago; bastard - (W.I.), Heliconia; water -, Alisma

Plantago L.

Platanaceae (EP., BH.). Dicots. (Archichl. Rosales; Unisexuales BH.). Only gen. Platanus (q.v.). Relationships obscure.

Platanthera Rich. (Habenaria p. p. BH.). Orchid. (II. 1). 80 N. temp.,

Platanus (Tourn.) L. Platanaceae. 5 N. temp., incl. the plane-tree, P. orientalis L. The bark scales off every year, leaving a smooth surface. The axillary bud is developed under the base of the petiole, which fits over it like an extinguisher. The stipules are united round the stem. Fls. monoec. in pend. heads, wind-fert. K, C 4 or 3, A 4 or 3, opp. sepals, G 4 or 3; ovules orthotr., pend. Multiple fr., each cpl. giving a caryopsis, often winged. Seed album. The wood of the plane is useful, and also that of the buttonwood of N. Am. P. occidentalis L.

Platycerium Desv. Polypodiaceae. 15 Afr., Malaya, Austr. (stag-horn
  ferns), epiph., or on steep rock surfaces. The rhiz. is short and bears
  alt. I. of two kinds. The young I. are protected by hairs. Of the
  two kinds of l., the one stands = erect (the 'mantle' l.), the other is
  pend., usu. much branched, and bears the sporangia in irreg, areas on
  its lower surface. Assimilation is chiefly carried on by the pend. I.
  Two types of mantle I. occur, repres. in P. grande J. Sm. and P.
  bifurcatum C. Chr. In the former the base of the I., which is un-
  branched, clings closely to the supporting trunk, whilst the upper part
  spreads out and makes a niche in which humus collects; in this the
  roots rainify and absorb food. In the latter the whole of the mantle
  1. clings to the support, and the only humus-supply is that furnished
  by the decay of old mantle 1. and perhaps of the tree bark; it grows
  in great colonies, owing to adv. budding from the r. In both the bases of the l. are fleshy. Cult. orn. Bower, Ferns, iii, 232.

(II. I). 6 N. Am. Podostemaceae (EP. and BH. incl. Tristichaceae). Dicotyledons (Archichl. Rosales; Multiovulatae aquaticae BH.). 22 gen., 100 sp. trop. A remarkable fam. of plants living only in rushing water, and growing only on rocks in rivers. The morphology of the veg. organs is extremely varied and complex. The seeds are shed on the rocks during the drier season of the year, and germinate when the rains cause them to be submerged. The primary axis is usu. small, and from the base there buds out a green thallus, usu. of adv. root nature. In Podostemon, &c. it is ± filamentous, creeping on the rock, and attached to it by hairs or exogenous projections termed haptera. In Dicraca it is \(\pm\) freely swimming and often ribbon-like or sea-weed-like. In Hydrobryum it is ± flattened, creeping, lichen-like. Other complications occur in Castelnavia and others. From the thallus in most cases endogenous secondary shoots arise, and remain veg. (l. alt., simple or much divided) till the latter part of the rainy season, when they form fls. which open when exposed by the fall of the water. The plants die after shedding their seed, unless an early rise of water occurs. Their outer tissues are usually very siliceous. Fls. simple, ¥, reg. or not, naked, enclosed in a spathe, hypog. A 1-2-∞, G usu. (2) 2-loc. with thick axile plac. Ovules ∞ (exc. Farmeria), anatr. Caps.; exalbum. seeds. The more dorsiventral the veg. organs, the more dorsiventral in general is the fl., the phenomenon showing progressively in A, G, fr., seed, and embryo. Chief genera: Rhyncholacis. Mourera, Podostemon, Dicraea, Hydrobryum, Castelnavia. [For full details see Willis in Ann. Perad. 1, 1902 and literature there quoted.] Podostemon Tul. Podostemaceae. 12 trop. and subtrop. Pollia Thunb. Commelinaceae. 16 palaeotrop.

Pollichia (Soland. in) Ait. Caryophyll. (1. 4). 2 trop. and S. Afr.

Pollination, the placing of pollen upon the stigma or ovule, may be effected by wind, animals, or water, and may be cross or self-fert. Wind-pollinated fis. (class W) show abundance of pollen, ripening simultaneously, dry and incoherent, freely accessible to the wind (catkins, pend. sta., explosive anthers, &c.); large much-branched stigmas to catch it; often flowering before the l. appear, &c.; Artemisia, Betulaceae, Calluna, Carex, Casuarina, Coniferae, Corylus, Cycadaceae, Cyperaccae, Elacagnaceae, Empetrum, Fraxinus, Gramineae, Humulus, Juglandaceae, Juncaceae, Littorella, Mercurialis, Myrothamnaceae, Platanus, Potamogeton, Quercus, Rumex, Sparganium, Spinacia, Thalictrum, Triglochin, Typhaccae, Ulmaccae, Urticaceae, Žea. Pollination by animals is usu. by insects; the most important are Coleoptera (beetles), very short tongued, Diptera (flies), mostly snort tongued, but the Syrphidae or hover-flies long tongued and clever at finding concealed honey, Hymenoptera (ants, wasps, bees, &c.) all short tongued but the bees, and Lepidoptera (butterflies and moths) all long tongued. Other animals are very rarely employed; bats in Freycinetia. Cf. Flower classes, Floral Mechanisms. Pollination by water in Ceratophyllum, Enhalus, Najas, Ruppia, Vallisneria, Zannichellia, Zostera, &c.; legitimate and illegitimate, Lythrum, Primula.

Pollinia Trin. Gramineae (2). 40 warm | #.

Pollinium, a number of pollen grains united into a mass (a definite number of masses per anther), Asclepiad., Orchid.

Polpoda C. Presl. Phytolaccaceae (Aizoaceae BH.). 1 S. Afr.

Poly- (Gr. pref.), many-; -adelphous, -androus, &c.; -carple, fruiting many times; -embryony, formation of > 1 embryo in an ovule; -gamy, &, &, and ? fls. in various combination on one or more pl. Polygala (Tourn.) L. Polygalaceae. 475 cosmop. exc. N.Z., Polynes., and Arctic zone. A few have stipular thorns. P. vulgaris L. (milke wort), in Brit. The fls. owe their conspicuousness to the two coloured sepals; they occur in three colours, red, white, and blue, usu. on different plants but sometimes on the same. The essential organs in most sp. are contained in the keel and emerge from it, as in Leguminosae, when it is depressed by a visiting insect. P. Senega L. (Senega snake-root) in N. Am. is medicinal.

Polygalaceae (EP., BH.). Dicots. (Archichl. Geraniales; Polygalinae BH.). 10 gen., 700 sp., cosmop. exc. N.Z., Polynes., and Arctic zone. Herbs, shrubs, or small trees with simple entire alt. opp. or whorled usu. exstip. 1.; the stipules when present are usu. thorny or scaly. Infl. a raceme, spike, or panicle, with bracts and bracteoles. Flr. diplochlam., medially +. K usu. 5, rarely (5), the 2 inner sepals (alae) often large and petaloid; C 5, rarely all present usu. only 3—the lowest and two upper—± joined to sta. tube, the median ant. petal keel-like and often with a term. brush; A in two 5-merous whorls, u u. only 8, or 7, 5, 4 or 3, usu. united below into an open tube; G (5—2), usu. (2), antero-post., 2-loc. with 1 anatr. pend. ov. in each loc. (rarely 1-loc. with ∞ ov.). Caps. nut or drupe. Endosp. or not. The fl. mech., like the structure, resembles that found in many Leguminosae (cf. Krameria). Chief genera: Polygala, Securidaca, Xanthophylum. For floral diagram see p. 529.

Polygaleae (BH.) = Polygalaceae.

Polygalinae (BH.). The 3rd order of Polypetalae.

Polygonaceae (EP., BH.). Dicots. (Archichl. Polygonales; Curvembryae BH.). 40 gen., 750 sp., chiefly N. temp.; a few trop., arctic,

and southern. Most are herbs whose 1. (exc. Eriogoneae) possess a peculiar sheathing stipule or ochrea (ocrea) clasping the stem above the leaf-base. This forms a char. feature of the fam. The infl. is primarily racemose, but the partial infls. usu. cymose. [See Eriogonum.] Fls. &, reg., cyclic or acyclic. The former have usu. the formula P 3+3, homochlamydeous; A 3+3, G (3); but many vary from this type. Oxyria is 2-merous; others, e.g. Eriogonum, Rheum, have branching of the outer sta. The acyclic fls. have P 5, arranged according to the 2/5 phyllotaxy (e.g. Polygonum), A 5-8, G (3). Ovary 1-loc. with 1 erect orthotr. ov. and a styles. Fls. pollinated by wind or by insects. Fr. almost always a triangular nut, with smooth exterior. The seed contains

Floral diagram of Polygala myrtifolia (after Eichler); the gland d as in P. Chamaebu us. Petals and bracts black, the missing petals represented by dotted lines, the missing sta. by ".

an excentric curved or straight embryo surrounded by mealy endosp, sometimes runinate. The fruits are usually wind-distributed; the persistent P usu. forms a membranous wing. Others are provided with books.

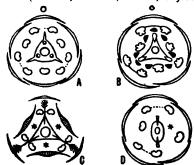

Classification and chief genera (after Dammer) :

A. Flower cyclic, endosp. not ruminate.

. RUMICOÍDEAE.

1. Eriogoneae (no ochrea): Chorizanthe, Eriogonum.

2. Rumiceae (ochreate): Rumex, Rheum, Oxyria.

Floral diagrams (after Eichler). A, Rheum; B, Polygonum tataricum; C, Russi; D. Polygonum tataricum. Bracta and bracteoles are conitted, and E and D the axis also. Glands in B shaded. The asterisks represent missing sto

B. Acyclic (except a few Coccoloboideae).

I. POLYGONOIDEAE (endosp. not ruminate).

1. Atraphaxideae (shrubs): Calligonum.

2. Polygoneae (herbs): Polygonum, Fagopyrum.

III. COCCOLOBOIDEAE (ruminate).

1. Coccolobeae (usu. 9): Muehlenbeckia, Coccoloba.

2. Triplarideae (usu. dioec.): Triplaris.

Polygonales. The 16th order of Archichlamydeae. Cf. p. xiv.

Polygonatum (Tourn.) Adans. Liliaceae (VII). 30 N. temp.; 3 in Brit. (Solomon's seal). There is a sympodial fleshy rhizome, upon which the annual shoots leave curious seal-like marks when they die away. Infl. unilat.; fl. homogamous, bee-pollinated.

Polygonella Michx. Polygonaceae (11. 2). 6 N. Am. Polygoniflorae (Warming). The 5th order of Choripetalae.

Polygonum (Tourn.) L. Polygonaceae (11. 2). 275 cosmop., but esp. temp. (11 in Brit., knot-grass, bistort, &c.); herbaceous. Some are xero., some water plants (e.g. P. amphibium L., which may however be found almost as often on land, where its l. have not the stalks of the water form). The fls. are in spikes and panicles (the partial infl. is cymose). Fls. \$\forall \, acyclic, usu. with a coloured 5-leaved P and about 8 sta. Honey is secreted at the base of the sta., and the fls. are visited by insects, but in varying degree (see the series of sp. described by Müller in Fert. of Fls. p. 509). Cleistog. fls. are found under the ochrea in P. aviculare L., &c. In P. viviparum L. (alpine Brit.) many of the fls. are replaced by bulbils in the lower part of the infl. (cf. Lilium, Allium). [P. Fagopyrum L. = Fagopyrum.]

Polyplethia Van Tiegh. (Balanophora p.p.). Balanoph. 3 Indomal. Polypodiaceae. Filicales Leptosporangiatae, q.v. for more detail. 130 gen. with 3000 sp., cosmop., rare in dry regions (see Nat. Pfl. for details of geogr. distr.). Mostly herbaceous perennials with a creeping rhizome or ± erect root-stock; many epiphytic. Leaves usu. large and pinnate, with sori on the lower sides. Each sorus consists are

and pinnate, with sori on the lower sides. Each sorus consists usu. of a large number of stalked sporangia, each with a vertical incomplete annulus and dehiscing transversely. An indusium may or may not be present. Cf. Bower, Ferns, especially vol. iii.

Classification and chief genera (after Engler):

- Woodsieae (sori term. or dorsal; indusium inf., extrorse or opening every way; spores bilateral); Woodsia, Cystopteris. Onoclea.
- Aspidieae (sori usu. on backs of nerves; indusium sup. or o: 2. spores bilateral; I. usu. unjointed): Dryopteris, Polystichum.
- Oleandreae (sori as in 2; indusium kidney-shaped, oblique; spores kidney-shaped; L divided): Oleandra.
- Davallieae (sori on or near edge of a segment, with extrorse indusium): Nephrolepis, Lindsaya, Davallia.
- Asplenieae (sori long or linear, unilat. along fertile nerves, with lat. indusium): Blechnum, Asplenium, Scolopendrium.
- Pterideae (sori usu. long, term. or along fertile nerves: usu. without indusium, or edge of l. rolled back): Gymnogramma. Cheilanthes, Adiantum, Pteris, Pteridium.
- 7. Vittarieae (sori at edge or on nerves | midrib; L unjointed): Vittar**ia.**
- Polypodieae (sori usu. roundish at end of a nerve; dead l. falling completely and leaving a scar): Drymoglossum, Polypodium, Cyclophorus, Drynaria.
- Acrosticheae (lower side of l., in whole or part, covered with sporangia; no indusium): Elaphoglossum, Platycerium.

(cf. Rubus) in Brit. (pond-weed). Water pl. with creeping sympodial rhiz. and erect leafy branches; all submerged or some floating. series of types occurs, beginning with the floating sp. and ending with the narrow-leafed submerged ones. There can be no doubt of the origin of the P. from land pl., and Schenck looks upon P. natans L. as the sp. least modified to suit a water existence, i.e. the nearest to the ancestral type. The upper l. are ovate, leathery, and float; the lower submerged, sometimes linear. Then come such as P. heterophyllus Schreb. where the submerged l. are all narrow. Next P. lucens L., P. crispus L., &c. with all the l. lanceolate and sub-merged. Then in P. obtusifolius Mert. et Koch, P. pusillus L., &c., the leaves are narrow and of a long ribbon shape. P. trichoides Cham. et Schlecht. represents the most

Flowering shoot of Potamogeton natans, reduced. A.-E. P. crispus.
A. Flower, enlarged. B. Single stamen, showing petaloid connective, enlarged. C. A fruit, enlarged. D. Embryo; d, hypocotyl; c, cotyledon, the letter points to the top of the sheath which encloses the plumule. E. Floral diagram. A, B, D, after Le Maout and Decaisne; E, after Eichler.

highly modified type (easily studied in a herbarium).

Hibernation in various ways; some green all winter; P. natans, &c. die down, leaving rhiz.; P. pectinatus L. forms tubers on special branches; P. crispus and others form winter buds with broad 1. (not closely packed); P. obtusifolius ordinary winter buds. Fls. simple, in subaerial spikes. A 4, in two whorls, G 4. From connective of each sessile anther there grows out a cup-shaped expansion simulating a P-leaf. Fl. protog., wind-fert. The outer layer of pericarp contains air, so that achene floats and may be distr.

Potamogetonaceae (EP.; Naiadeae p. p. BH.). Monocots. (Helobieae; Apocarpae BH.; pp. iii, liv). 9/120, cosmop.; water pl., some marine. Usu. creeping stem or rhiz., mono- or sym-podial, attached to soil by adv. r., with erect branches upwards into water, usu, with ribbon l.. submerged (exceptions in Potamogeton), usu. alt. in 1 phyllotaxy. Base sheathing; within sheath are the small scales (squamulae intravaginales) which occur in most Helobicae. Spike, cyme, or sol. fls. No true P, exc. Zannichellia ? and Althenia; Posidonia and Potamogeton show Laf-like outgrowths from sta. In some it is not easy to decide what is to be regarded as the fl. lef. Zostera). Fl. & or unisexual, reg., 1-4-merous; anthers sessile. sometimes connate; cpls. free, or 1 only, with 1 ov. in each, usu. pend. orthotr. Fr. 1-seeded; embryo usu. with well-developed hypocotyl; no endosp. Diagram, &c. on p. 534, and of. genera.

Classification and Genera: [Monograph in Pfl. R., 1907].

A. Fls. in spikes, often \(\):

1. Zostereae (axis of spike compressed, flat; marine): Zostera (cpl. rounded at base, fl. &), Phyllospadix (cpl. cordate at base; 3 ?).

Posidonieae (axis of spike terete; spike branched; marine):

Potamogetoneae (axis at last; spike simple; fresh or brackish water): Potamogeton (spike cylindrical, A 4), Ruppia (spike 2-fld., A 2).

Fls. sol. or in cymes, & Q.

Cymodoceae (P none; pollen filiform; marine): Cymodocea (stigmas 2), Diplanthera (stigma 1).

5. Zannichellieae (P in ? fls.; pollen globose; fresh or brackish water): Zannichellia (& with no P; cpls. usu. 4), Althenia (& with cupuliform P; cpls. usu. 3).

Potamophila R. Br. Gramin. (6). 1 Austr.

Potaninia Maxim. Ros. (III. 2). 1 Mongolia. Epicalyx. K, C, A, 3, Potato, Solanum tuberosum L.; sweet-, Ipomoea Batatas Lam., [G I. Potentilla L. (incl. Comarum L., Tormentilla L.). Ros. (III. 2). 300, nearly cosmop., chiefly N. temp. and arctic. 9 in Brit., incl. P. Anserina L. (silverweed), P. reptans L. (cinquefoil), P. Tormentilla Neck. (tormentil), P. comarum Nestl., &c. Herbs, usu. with creeping stems rooting at nodes (veg. repr.). Fl. with epicalyx of small green l., outside and alt. with the seps. (the stips. of seps. united in pairs: often one or more may be seen with two lobes, or fully divided). Fls. of class AB, homogamous, visited by flies; honey secreted by ringshaped nectary within sta.

Poteranthera Bong. Melastom. (1). 4 Braz., Guiana. Fl. 5-merous.

Prim (Am.), privet, Ligustrum vulgare L.

Primine, outer coat of an ovule.

Primrose, Primula vulgaris Huds.; Cape., Streptocarpus; Chinese., Primula sinensis Sabine; evening., Oenothera; - willow (W.I.),

Jussieua.

Primula L. Primulaceae. 250 N. hemisph. chiefly in hilly districts. A few elsewhere, e.g. P. farinora L., var. magellanica Hook., at the Str. of Magelhaen. The rhizome is a sympodium, each joint terminating in an infl. In some sp. this consists of successive whorls of fls. arranged up a long stalk, e.g. japonica A. Gray. A few of the more important sp. are: P. sineusis Sabine, the Chinese primirose, P. elatior Hill, the oxlip (Brit.); P. vulgaris Huds. (P. acaulis Hill), the primrose (Brit.), P. veris Lehm. (P. officinalis Jacq.), the cowslip (Brit.), P. farinosa, L. (Brit.), P. japonica A. Gray, P. Auricula L., the auticula with its many forms. A great many hybrids occur, and garden vars. In the double crowned cowslip the K has become petaloid, so that the fl. looks as if it had two Cs, one within the other.

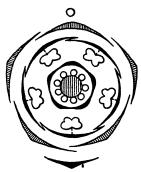

The fls. are dimorphic, heterostyled. On one pl. are long-styled fls. with sta. halfway up the tube and the stigma at its mouth; on another plant are short-styled fls., with stigma halfway up and anthers at the mouth. The depth and narrowness of the tube suit the fl. to bees or butterflies, and these tend to carry pollen from long state to long style or from short to short. These 'legitimate' pollinations (see Lythrum) which are at the same time crossings, are the only ones which produce a full complement of fertile seed.

The fl. stalks in umbellate forms, e.g. cowslip, stand close and erect till the fls. open, then spread out, and close up again as the fr. ripens; thus the caps. is held erect and the seeds must be shaken out.

Primulaceae (EP., BH.). Dicots. (Sympet. Primulales). 25 gen., 550 sp. cosmop., but esp. N. temp. 9 Brit. genera. Herbaceous pl., commonly perenn., with rhiz. or tubers; l. opp. or alt., exstip. Fls. often borne on scapes, which when > 1-flowered are term.; they are usually actinom., y, often heterostyled, and 5-merous, without bracteoles, the odd (4th) sepal post. K (5) persistent; C (5), reg. (exc. Coris), or 5, or o (Glaux); A 5, epipet. and opp. the pets.; occasionally g stds. alt. with the pets.; anthers intr. The presence of the stds. here

as in Myrsin. explains antepet. position of sta. as due to abortion of originally outer whorl. Formerly much discussion, esp. after Pfeffer's discovery of development of C from backs of sta (Eichler's (Bluthendiagramme). G or ½-inf., syncp. with free-central plac., typically of 5 cpls., but this is not easily proved, as there are no partitions (cf. Caryoph.), and style and stigma are simple; ov. usu. oo, spirally or in whorls on plac., 1-anatr. Caps. fr., 5-valved, usu. dehisc. by teeth at tip, one opp. each Seeds few or many: embryo small, in fleshy or horny endosp. 11. often heterostyled (cf. Primula, also Hottonia, Glaux, Androsace). No

Classification and chief genera:

Floral diagram of Primula acaulis (after Eichler).

Fl. reg.; K not spiny. Pl. without tubers.

econ. value; many cult. orn. fl.

I. Androsaceae (G; C imbr.): Primula (C not reflexed, lobes entire or bifid, sta. on tube, ov. ∞), Dionysia (do.; ov. few), Androsace (do.; tube very short), Soldanella (do.; lobes fimbriate, caps. operculate), Hottonia (water pl.), Dodecatheon (C reflexed).

3. Lysimachieae (G; C conv.): Lysimachia (caps. with valves; 5-merous), Trientalis (do.; 7-merous), Glaux (do.; apet.), Anagallis (caps. with lid).

Samoleae (G 1-inf.): Samolus only.

Pl. with tubers.

Protanthera Rafin. Liliaceae. Nomen. 2 N. Am.

Protarum Engl. Araceae (VII). I Seychelles.
Protea L. Proteaceae (I). 75 S. and trop. Afr. Fls. in showy heads, often with coloured bracts.

Proteaceae (EP., BH.). Dicotyledons (Archichl. Proteales; Daphnales BH.). 50 gen., 060 sp. "which have a very char. distr.; there are in Austr. 591, trop. E. As. 25, New Caled. 27, N.Z. 2, Chili 7, trop. S. Am. 36, south-west Cape Col. 262, Madag. 2, Mts. of trop. Afr. 5 (Engler). The great majority live in regions where there is annually a long dry season. Correlated with this is the fact that they are mostly xero. Nearly all shrubs and trees with entire or much-divided exstip. 1., which have commonly a thick cuticle and often a covering of hairs further checking transpiration. The fls. are borne in racemes, spikes, heads, &c., and are often very showy; many have their pollen freely exposed, though they are not wind-fert.—a peculiarity perhaps connected with their life in a dry climate (compare the Acacias of Australia).

The fis. are usu. &, often +. P (4), corolline, valvate; the I. commonly bent or rolled back when open; sta. 4, inserted on the tepals, and usu, with only the anthers free: G 1, ovules many or few or one, pend. or not, the micropyle facing the base of the ovary. Style term., long, often bent inwards. Follicle, capsule, drupe or nut; seed The ovary is sometimes borne on a gynophore and at its base are commonly nectarial outgrowths. The fis. are protandious and adapted to insect-fert.

Classification and chief genera (see discussion in Nat. Pfl.):

I. PERSOONIOIDEAE (fls. single in axils of bracts; ovules single, few or 2; drupe or nut, one seeded): Persoonia, Protea, Leucadendron.

GREVILLOIDEAE (fls. in pairs; ovules several or 2; fr. usu. dehisc., many seeded): Grevillea, Hakea, Banksia.

Proteales. The 13th order of Archichlamydeae. Cf. p. xii.

Protection against grazing animals is obtained by stinging hairs (Lonsaceae, Urticaceae, &c.), by prickles, &c., or by disagreeable taste; - of buds, see Bud; - of honey, cf. Flower-classes; - of flowers, see Flower-movements; - of leaves, see Movements; - of young leaves, Amherstia, Brownea, &c.

Proteids, complex organic bodies, containing C, H, O, and N.

Proteocarpus Börner = Carex L. p.p. (Cyper.).

Psilotaceae. Psilotales. Two gen. (Psilotum, Tmesipteris) with 4 sp. trop. and subtrop. The mature sporophyte has no roots, their functions being performed by the branched thiz. The aerial branches bear only scale-l. in Psilotum. The sporangia are 2- or 3-loc., borne on small two-lobed sporophylls. "There has been much disagreement as to the morphological nature of the sporangiophores of the Psilotaceae. The two chief views are the following: (1) that the whole sporangiophore is a single foliar member; (2) that it is a reduced axis bearing a terminal synangium and two 1. The recent very careful researches of Bower upon the origin of the sporangiophore and synangium confirm the former view" (Campbell; see also Bower in Phil. Trans. CLXXXV, 1894, p. 473).

The fully-developed synangium (2-loc. in Tmesipteris, 3-loc. in Psilotum) has the outer walls of the loculi composed of a superficial layer of large cells, beneath which are several layers of smaller ones. The cells composing the septa are narrow tabular ones; occasionally the septum is partially absent....Bower regards the whole synangium as homologous with the single sporangium of Lycopodium" (Campbell). For prothallus see Trans. R. S. Edinb. 1918 (2 papers), Phil. Psilotales. The 5th class of Pteridophyta. Trans. B, 213, 1025.

Psilotrichum Blume. Amarantaceae (2). 15 palaeotrop.

Psilotum Sw. Psilotaceae. 3 warm. They are probably ± saprophytic in their habit, and have neither roots nor green l., but only green stems. See fam. for details of sporangia, &c. Veg. repr. is common, small gemmae being formed upon the rhiz. At first no structural differentiation is visible in these, but apical cells are formed later.

Pteriohis Lindl. Orchulaceae (II. 2). of trop. S. Am.
Pteridium Gled. I cosmop., P. aquilinum Kuhn, the bracken. It has a creeping rhiz., bearing 2 ranks of l. At the base of the l. is a nectary, which ants visit. The sori are confluent along the l. margin, which is curved over them, while there is also a true indusium on the inner side of the sori (the char. of distinction from Pteris, in which the bracken used to be placed). Adv. buds appear on the back of the l. stalk, near the base.

Pteridocalyx Wernham. Rubiaceae (1. 3). 2 Brit. Guiana. Pteridophyllum Sieb. et Zucc. Papaveraceae (1). 1 Japan.

Pteridophyta. Vascular Cryptogams, one of the four chief divisions of the Vegetable Kingdom. They have a well marked alternation of generations, the gametophyte (oophyte or sexual generation) being insignificant in size compared to the sporophyte (asexual generation), but still capable of independent growth. The life history of a typical Pteridophyte may be shown diagrammatically as follows, taking the fern as an example:

Fern-plant - sporophylls - sporangia - spores

fertilised ovum - {
 spermatozoid - antheridia | ovum - archegonia | rothallus.

The 'plant' or asexual generation alternates with the prothallus or sexual generation. In many P. there are 3 and 2 prothalli. The prothallus corresponds to the 'plant' in a moss or liverwort, whilst the sporogonium of these latter='plant' in a fern or lycopod.

The plant itself takes various forms in the different groups. Except in tree ferns and in fossil forms it does not attain great size. There is an erect stem in many ferns, &c.; others have creeping stems (s.g. Lycopodium and Selaginella), rhiz. (many Ferns), or flowing

w.

stems (Hydropterideae). The l. are simple, except in many ferns. There is no primary tap-root, but roots are formed as required from the stem or l. Internally there are well marked vascular bundles in both stem and leaf, and many anatomical features of fig. pl. may be found here also.

The sporangia arise upon the l., either on the ordinary foliage as in most ferns, or on specially differentiated l. as in Osmunda, Equisetum, Lycopodiales, Hydropteridineae, &c. They may be sol. or in groups (sort); in the latter case often protected by a special outgrowth of the l., the indusium. The spores are formed by a complicated process from a single cell or row or layer of cells—the archesporium—inside the sporangium: each has a thick waterproof outside wall. The spores may be of one kind only, in which case the plant is termed homo- or iso-sporous, or of two kinds (heterosporous), when the smaller spore is termed the microspore, the larger the megaon macro-spore; the former gives rise to a 3 prothallus, the latter to a?.

Falling upon the soil (or into the water, in the case of the Hydropteridineae) the spores germinate under suitable conditions, giving rise to the sexual plants or prothalli. The prothallus is a small body without distinction into stem and I.; it absorbs materials from the soil (usually by rhizoids) and, being green, assimilates in the It bears the sexual organs—antheridia (3) and ordinary way. archegonia (?). In the homosporous forms these are both found on the same prothallus, except in Equisetum, where, though the spores are absolutely similar so far as we can tell, there are separate & and ? prothalli, as in the heterosporous forms. In the antheridia are developed the motile a cells or spermatozoids. Fert. takes place by aid of water. The mucilage contained in the neck of the archegonium is attractive to the spermatozoids, which swim up the neck of the archegonium. One of them finally fuses with the ovum or ? cell at the base of the archegonium, and the fertilised ovum (zygote) then develops into a new 'plant' or asexual generation, being nourished by the prothallus until it can assimilate for itself.

Classification (after Engler):

 Filicales. L. usu. more strongly developed than stem, often big and much branched, usu. circinate in vernation. Sporangia on normal or special 1., on edge or lower side, usu. in sori. Spermatozoid polyciliate.

1. Filicales Leptosporangiatae.

2. Marattiales.

3. Ophioglossales.
[II. Sphenophyllales. Fossil plants only.]

III. Equisetales. Homosporous (some fossils heterosporous), with dioec. prothalli. Stem much branched with jointed internodes and small sheathing whorls of l. (not green). Sporangia on peltate sporangiophores, forming a term. spike. Spermatozoids polyciliate.

IV. Lycopodiales. Homosporous or heterosporous; in the latter case the ? prothallus remains enclosed in the spore till fert. Stem simple or branched; l. many, small, usu. alt., entire. Sporangia singly on upper side of leaf-bases, or in their axils. Spermatozoids biciliate.

Lycopodiales eligulatae.

Lycopodiales ligulatae.

V. Psilotales. Sporophylls bipartite. Sporangia 2-3-loc. Spermatozoids biciliate.

VI. Isoetales. Stem short, growing in thickness, with numerous long I. with ligula over a basal groove, in which is a sporangium; megaspores on outer sporophylls, microspores on inner. Spermatozoids polyciliate.

Cycadofilices. Fossil plants only.]

Pungens (Lat.), sharp-pointed.

Punica (Tourn.) L. Punicaceae (only genus). 2, one in Socotra, the other, P. Granatum L., the pomegranate, from the Balkans to the Himalayas, and cult. The young twigs have four wings, composed simply of epidermis and cortical parenchyma; these are early thrown off. The fl. is \(\frac{1}{2}\), reg., perig. K 5—8, valvate; C 5—8, imbr.; A \(\infty\); G adnate to receptacle. The mature ovary has a peculiar structure, due to a development like that in Mesembryanthemum. Two whorls of cpls. with basal plac. are laid down, and then a peripheral growth tilts them up from $\|\cdot\|$ to $=\cdot=$ so that two layers of loculi are formed and the placentation appears to be parietal. Ovules ∞, anatr. The arrangement is also seen in the fr., commonly termed a berry, but not strictly so. The pericarp (axial in part) is leathery, and the fleshy inner part round the seeds is really the outer layers of the seed coats. No endosp.

Pyrene, a single stone of a drupe.

Pyrethrum Hall. = Chrysanthemum Tourn. (Comp.).

Pyriform, pear-shaped.

Pyrola (Tourn.) L. (incl. Moneses Salisb.). Pyrolaceae. 15 N. temp. (5 Brit., wintergreen). Evergreens with creeping stocks. P. (Moneses) uniflora L. has adv. buds on the roots, and a solitary term. fl. The fls. of P. minor L. are in racemes, pend., without discs. There is no honey; the stigma projects beyond the anthers, but pollen may at last fall upon it from them. P. rotundifolia L. is similar. The seeds of P. are very light and are distr. by wind.

Pyrolaceae (EP.; Ericaceae p.p., Monotropeae BH.). Dicots. (Sympet. Ericales). 10 gen., 30 sp., cold N. temp. and arctic. The two Brit. genera represent the two types of habit found in the order—evergreen plants with sympodial growth from rhiz. (Pyrola), and saprophytes (Monotropa). The infl. is term.; it may be a true raceme (Pyrola), or a cyme, leafless or with scaly bracts. Fl. 2 actinom. K 4-5; C (4-5) or 4-5; A 8-10, obdiplost.; $\underline{G}(4-5)$. The petals and sta. are often at the edge of a nectariferous disc. Anthers intr., opening by apical pores or transv. valves; pollen simple or in tetrads. Cpls. opp. petals; ovary imperfectly 4—5-loc. Style simple; ovules minute, ∞ , anatr., on thick fleshy plac. Capsule. Seeds ∞ , small, in loose testa. Embryo of few cells, without differentiation of cotyledons. Chief genera: Pyrola, Chimaphila, Monotropa, Sarcodes. BII. unite Pyrola and the green-leaved forms to Ericaceae, making a fam. Monotropeae for the saprophytes.

Pyronia × Veitch. Rosaceae. Hybrid, Pyrus-Cydonia (pear and quince).

See Journ. of Hered. 1916, p. 416.

Pyrularia Michx. Santalaceae. 2 N. Am., Himalaya.

Pyrus (Tourn.) L. (BH. incl. Cydonia, Mespelus). Rosaceae (11). 65 N. temp.; 6 in Brit., incl. P. Aucuparia Ehrh., the rowan or mountain ash, P. Malus L. the apple, &c. The recept is hollowed out and united to the syncarpous ovary. The fls. are protogynous, and are visited by bees and many other insects. Several var. of pear (P. communis L.) are self-sterile. After fert, the fr. becomes a large fleshy pseudocarp (ponie), the flesh consisting of the enlarged recept., while the gynaeceum forms the core. Several are cultivated for their truit, e.g. P. Malus L. (apple), P. communis L. (pear), P. germanica Hook. f. (medlar). P. japonica Thunb. is often grown upon walls.

Ranalisma Stapf. Alismaceae. 1 Selangor.

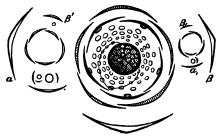

Randia Houst. ex L. Rubiaceae (1. 8). 125 trop. The two l. at a node are often unequal and one frequently aborts early. Thorns often occur. In R. dumetorum Lam. the thorn arises in the axil above the bud, and is carried up by intercalary growth.

Randonia Coss. Resedaceae. 1 Algeria.

Ranevea L. H. Bailey (Ravenea H. Wendl.). Palmae (IV. 1). 1 Comoros.

Ranunculaceae (EP., BH.). Dicots. (Archichl. Ranales). 40 gen., 700 sp., chiefly N. temp. and well repres. in Brit. Most are herbaceous perennials with rhiz., usually of condensed (100t-stock) form, and always sympodial. Each year's shoot ends in an infl. and a bud is formed in the axil of one of the l. at the base, which forms the next year's growth. In most the primary root soon dies away, and adv. roots are formed from the stem; often (e.g. Aconitum, Ranunculus sp.) these swell up into tubers holding reserve materials. L. exstip., usualt., with sheathing bases and often very much divided. The chief exceptions to the above general statements, and special cases of interest, are described under the genera, e.g. Helleborus, Eranthis, Clematis, Ranunculus.

The infl. is typically determinate; in Anemone sp., Eranthis, &c., a single term. fl. is produced. More often a cymose branching occurs, the buds in the axils of the l. below the term. fl. developing in descending order. In Nigella sp. and others, after the term. fl. is formed, the buds below develop in ascending order, so that a raceme with an

Ranunculus acris. Floral diagram of axillary dichasial cyme, with details of primary fl. Sta. according to the $\frac{8}{21}$ phyllotaxy. a β bracteoles of primary, a' β' , a, β , of later, fls. After Eichler.

end fl. is formed; in Aconitum, &c. the same thing occurs, but the term. fl. rarely develops. In Nigella, Anemone, &c., there is an invol. of green leaves below the fl., usually alt. with the K.

Fl. itself typically spiral upon $a \pm elongated$ recept., but frequently the l. of the P in whorls; usu. reg. and v. The P usu. petaloid; rarely (e.g. Ranunculus) a true K and C. Frequently there occur nectaries of various patterns between the P proper and the sta.; these are usu. considered as modified petals, but it is as probable that they are derived directly from sta. An interesting series of transitions may be seen by comparing the following fls.: Caltha (honey secreted by cpls., 'calyx' present, nothing between it and sta.), Helleborus or Eranthis (honey secreted in little tubular 'petals'), Nigella (ditto, but 'petals' with a small leafy end), Ranunculus auricomus ('petals' distinct and coloured, with pocket-like nectary at base), R. acris, &c. (petals large, nectary at base). In Aconitum and Delphinium there The sta. are usu. ∞ and spiral, the anthers extr.; the is a + fl. cpls. ∞, apocarpous, spiral, with either one basal or several ventral anatr. ovules. In Nigella the cpls. are united; there is only I in Actaea, which thus forms a link to Berberidaceae.

As a rule the fis. are protandrous, and the sta., as their anthers open, bend outwards from the centre. A series of fis. showing various grades of adaptation to insects may be found, e.g. Clematis (pollen fi.), Ranunculus (actinomorphic, honey scarcely concealed at

all), Nigella (honey in little closed cavities), Aquilegia (honey in long

spurs), Delphinium (ditto, but + also, and blue), &c.

Fr. a group of achenes or follicles (caps. in Nigella, berry in Actaea); seeds with minute embryo and oily endosp. The R. are mostly poisonous; a few, e.g. Aconitum, are or have been medicinal. Classification and chief genera (after Prantl):

A. Ovules many: follicle, berry or capsule.

I. Paeonieae (no honey leaves; fls. usu. sol.; ovary wall fleshy; stigma broadened): Paeonia.

2. Helleboreae (usually honey-leaves; ovary wall rarely fleshy and then fls. in racemes; fls. sol. or in cymes or racemes): Caltha, Trollius, Helleborus, Nigella, Eranthis, Actaea, Aquilegia, Delphinium, Aconitum.

B. Ovule one; achene.

3. Anemoneae: Anemone, Clematis, Ranunculus, Thalictrum.

Ranunculastrum Fourr. = Ranunculus Tourn. p.p. (Ranunc.).

Ranunculus (Tourn.) L. Ranunculaceae (3). 300 cosmop., esp. N. temp.; 15 in Brit. R. Ficaria L. (pilewort or celandine) has tuberous roots, one formed at the base of each axillary bud; these may give rise by separation to new plants. R. aquatilis L. (water crowfoot) is often divided into a large number of so-called species; it has a floating stem bearing I. which in many are of two kinds (heterophylly), the submerged I. being much divided into linear segments, whilst the floating I. are merely lobed. R. repens L. (creeping buttercup or crowfoot) has creeping runners which root at the nodes and give rise to new pl. R. acris L. and R. bulbosus L. are other common buttercups; the latter has the base of the stem thickened for storage. Fls. in cymes, reg., with well-marked K and C (see fam. for diagram), protandrous and visited by a miscellaneous lot of insects (class AB). Honey is secreted in little pockets at the base of the petals.

Receptacle, the portion of stem upon which the fl. (or infl.) is actually borne. According to its form the ovary may be superior or inferior, the fl. hypo-, peri-, or epi-gynous (q.v. and see fig.).

DIAGRAMMATIC LONGITUDINAL SECTIONS OF FLOWERS, to show types of recaptacle, ovary, stigma &c. A, hypog. fl. with uniloc. ovary, parietal plac. and unimerous ascending anatr. ovules with raphe downwards; stigma sessile, bilobed. By perig. fi. with multi-loc, ovary, axile plac, and numerous horiz anatr. ovules with raphe upwards; style with bifd stigma. C, epig. fi. with multi-loc. ovary, axile plac, and sol, pend anatr. ovules with ventral raphe; style long with capitate stigma. r, recept.; r, calyx; c, corolla; a, stamens; o, ovary; st, stigma.

Fl., or P, K, C, A, may be hypo-, peri- or epi-gynous; the G superior or inferior. Perig. fls. may be shallowly or deeply perig.; in the latter case the tube is described as to length, texture, &c. There may be a disc in the fl. Sometimes outgrowths (effigurations) of the recept are seen, e.g. in Passiflora, Capparidaceae, Orchidaceae, &c. Sometimes the recept. elongates between the whorls of floral members, e.g. in Lychnis between K and C, in Passiflora and in many Capparidaceae between C and A, in Capparis between A and G. If the elongated portion bears the sta. it is termed an and ophore, if only the cpls., a gynophore. Other receptacular outgrowths are seen in epig. flowers, e.g. the wings on the inf. ovary of Begonia, the thorns (which sometimes bear fls.) on that of Tetragonia, the nectariferous disc of Umbelliferae, &c, and so on.

Rectipetality, tendency to grow in a straight line.

apex. R. lutea L. (dyer's weld) yields a yellow dye.

Resedaceae (EP., BH.). Dicots. (Archichl. Rhoeadales; Parietales BH.). 6 gen., 60 sp., chiefly Medit., also in Eur., As., S. Afr., Calif. Most are xero. herbs with alt. stip. 1. and racemes of + ♥ fls., with bracts but without bracteoles., The axis develops post: into a large disc, and upon this side the petals, &c. are usu. better developed than upon the ant: side of the fl. K4-8; Co-8; A3-40; G(2-6) or 2-6, in the former case 1-loc. with parietal plac. Ovary open at the top; ovules 1-- per cpl., anatr. Fr. capsular; embryo curved; no endosp. Chief genera: Reseda, Oligomeris. Reserves, ef. Edible Products, Vegetative Reproduction, &c.

Resins, products of secretion or disintegration, usu. formed in special cavities or passages; collected by tapping. Insoluble in water, soluble in alcohol, ether, or carbon disulphide; burn with a sooty flame. Roughly divisible into hard resins proper, gum-resins or mixtures of gum and resin, and balsams, fluid resins or resins dissolved in ethereal oils. Resins are derived from the distillation of the turpentines of Coniferae, &c., the hard copals or animes from Agathis, Hymenaea, Trachylobium, &c., the dammars from Canarium and other Burseraceae, Shorea and other Dipterocarpaceae, Dracaena. Guaiacum, Protium, Rhus, Xanthorrhea, &c. Gum-resins from Boswellia (frankincense), Calophyllum, Convolvulus, Dorema, Ferula, Garcinia (gamboge), &c. Balsams from Burseraceae (esp. Canarium), Commiphora, Coniferae (turpentines), Copasfera (balsam of Copaiba), Dipterocarpus, Liquidambar, Melanorrhoea, Myroxylon (balsam of Peru, Tolu), Opoponax, Pistacia (Chian turpentine, mastic), Populus, Styrax, Vateria, Vatica; -passages, channels in which resin flows. Barry, Drummond and Morrell, Resuns, 1926.

Respiration, absorption of O and evolution of CO₂; cf. Aerenchyma.

Rest harrow, Ononis.
Restans (Lat.), persistent.

Restiaceae (BH.) = Restionaceae.

Restiaria Lour. Inc. sed. 1 China.

Restio L. Restionaceae. 110 S. Afr., Austr. Assimilation is performed by the green stems, the l. being reduced to sheaths.

Restionaceae (EP., BH.) Monocots. (Farinosae; Glumaceae BH.). 19 gen., 250 sp., mostly in S. Afr. and Austr., a few in N.Z., Chili and Cochin China. Xero., usu. of tufted growth, with the general habit of Juneus; below ground is a rhiz. with scaly l., giving off erect cylindrical shoots bearing sheathing l. (rarely with ligules), which have a short blade, or sometimes none, in which case assim. is performed by the stem. Fls. dioec. (rarely monoec. or \(\mathbb{Y} \), reg., in spikelets. P in two whorls, but single members often absent; A 3 or 2, opp. to the inner perianth-1.; G(3-1), 1-3-loc., with 1 pend. orthotr. ov. in each. Caps. or nut. Embryo lens-shaped, in mealy endosp. Chief genus: Restio.

Restrepia H. B. et K. Orchidaceae (II. 8). 15 trop. Am.

Retama Rafin. = Genista Tourn. p.p. (Legum.).

Retanilla Brongn. Rhamnaceae. 6 Chili, Peru. Retinaculum, Acanthaceae, Asclepiadaceae, Zostera.

Retiniphyllum Humb. et Bonpl. Rubiaceae (1. 8). 10 trop. S. Am. Retinispora Sieb. et Zucc. = Thuya L., &c. Seedlings of many sp. of the genera Chamaecyparis, Cupressus, Thuya, &c., exhibit, instead of the decussate ppressed l. of the mature plant, spreading needle-l. (often in whorls of 4) like those of Abies, &c. (cf. Pinus, Acacia, &c.). If now these young seedlings be used as offsets, the new pl. thus formed retain throughout life this form of foliage; and pl. are thus obtained of totally different habit from that usual in these genera. To these 'seedling forms' the name R. was given. Many in gardens. The synonymy of some is: R. decussata hort. = Thuya orientalis: R. flifera Fowles = Cupressus obtusa; R. juniperoides Carr. = Thuya orientalis; R. obtusa Sieb. et Zucc. = Cupressus obtusa; R. pisifera

Sieb. et Zucc. = Cupressus pisifera; R. recurvata hort, and R. rigida Carr. = Thuya orientalis; R. squarrosa Sieb. et Zucc. and R. stricta hort. = Cupressus pisifera. For further synonymy see Index Kewensis. Retinodendropsis Heim. Dipterocarpaceae. 1 Borneo. Retting, rotting away the softer tissues, cf. Linum, Cocos. Retzia Thunb. Loganiaceae (Solan. BH.). 1 S. Afr. Reussia Endl. Pontederiaceae. 2 S. Am. Reutera Boiss. = Pimpinella Riv. p.p. (Umbell.). Reverchonia A. Gray. Euphorbiaceae (A. I. I). I Texas. Reys O. Ktze. (Burchardia R. Br.). Rhadamanthus Salisb. Liliaceae (v). 2 S. Afr.

Rhagadiolus Tourn. ex Scop. (BH. incl. Hedy/nois and Garhadiolus). Compositae (13). 1 Medit. Fr. linear, without pappus, completely enwrapped in an involucral bract.

Rhagodia R. Br. Chenopodiaceae (A). 12 Austr.

Rhamnaceae (EP., BH.). Dicots. (Archichl. Rhamnales; Celastrales BH.). 40 gen., 500 sp., cosmop. Mostly trees or shrubs, often climbing (by aid of hooks in Ventilago, tendrils in Gouania, &c., twining stems in Berchemia): thorns occur in some, and especially in Colletia, &c. (q.v.). In these pl. too, serial buds occur in the 1-axils. L. simple, usu. with stip., never lobed or divided. Infl. cymose, usu. a corymb.

Fl. inconspic., \$ or rarely unisexual, reg., sometimes apet. Recept. hollow, free from or united to the ovary. K 5-4, valvate; C 5-4, usu. small, often strongly concave, frequently clawed at base; A 5-4, alt. with sepals, usu enclosed by the petals, at any rate at first. Disc usu. well developed, intra-staminal; G free or ± united to recept., 3-2- (rarely by abortion 1-) loc. (sometimes 4- or typically 1-loc); in each loc. 1 (rarely 2) basal ovule with downwardly-directed micropyle; style simple or divided. Fr. dry, splitting into dehisc. or indeh.

mericarps, or a drupe with 1 or several stones, or a nut. Endosp. little or none. Many of the dry fr. show special adaptations for windcarriage, e.g. Paliurus, Ventilago. Closely related to Vitaceae, from which it is chiefly distinguished by the small petals, the recept., the endocarp and simple 1.; it also approaches Celastraceae, the chief distinction being the antepetalous sta. Few are of economic value; see Zizyphus, Rhamnus, Hovenia. Chief genera: Ventilago, Paliurus, Zizyphus, Rhamnus, Hovenia, Ceanothus, Phylica, Colletia, Gouania.

Rhamnales. The 25th order of Archichlamydeae. Cf. p. xxx.

Rhamneae (BH.) = Rhamnaceae.

Rhamnella Miq. (Microrhamnus BH.). Rhamnaceae. 1 Japan, China.

Rhamnidium Reissek. Rhamnaceae. 5 trop. S. Am., W.I.
Rhamnoneuron Gilg. Thymelaeaceae. 1 Tonquin.
Rhamnus Tourn. ex L. Rhamnaceae. 100 cosmop., 2 in Brit., R. cathartica L. (common or purging buckthorn) and R. Frangula L. (alder buckthorn). Shrubs with alt. or opp. l. and small cymose clusters of fls. Two sections. To § 1, Eurhamnus (fls. usu. 4-merous, polyg. or dioec.), belong R. Alateinus L. (Medit.) and R. cathartica (Eur., As., Medit.), whose berries are purgative; the juice of the fr. is mixed with alum and evaporated, thus forming the paint known as sap-green; also R. infectoria L. (Mts. of S. Eur.) whose berries (graines d'Avignon or 'yellow berries') yield useful green and yellow dye-stuffs, and R. chlorophora Decne. from whose bark the Chinese prepare the dye known as 'Chinese green indigo' used in dyeing silk (R. utilis Decne. is also employed). To § 2, Frangula (fls. usu. 5-merous, \$), belong R. Frangula (Eur., As., N. Afr.) whose bark is officinal (cathartic) and whose wood forms one of the best charcoals. R. Purshiana DC. in N. Am., whose bark (Cascara sagrada) is largely used as a cathartic, &c.

Rhamphicarpa Benth. Scrophulariaceae (III. 2). 8 palaeotrop.

Rhinanthus L. (incl. Fistularia L.). Scrophulariaceae (III. 3). 10 Eur., Medit., N. Am.; 2 in Brit. (yellow-rattle), common in damp pastures. Semi-parasites with loose pollen fls. (see fam.).

Rhinopteryx Niedenzu. Malpighiaceae (I). I Gambia.

Rhipidium, a monoch, cyme where each successive branch falls alt. on one side and the other of the relatively main axis, and all fis. are in one plane, Iris, Juncus.

Rhipogonum Forst. Liliaceae (XI). 5 E. Austr., N.Z.

Rhipsalis Gaertn. (incl. Hariota, Pfeiffera). Cactaceae (III. 3). Brazil, Argentina. R. Cassytha L. is found in Ceylon and Madag., but quite possibly introduced (the only cactus out of Am.; see fam.). Epiph., rarely thorny, sometimes of Cereus-like structure, sometimes Phyllocactus-like, or with cylindrical stems (compare sp. of Euphorbia). Fr. fleshy.

Rhiz- rhizo- (Gr. pref.), root; -carp, pl. with sporangia on root-like processes, Marsileaceae; -me, see separate article; -ophore, Selaginella.

Rhizanthemum Van Tiegh. (Loranthus p.p.). Loranth. (1). 2 Malaya. Rhizanthous, flowering from the root.

Rhizoboleae = Caryocaraceae.

Rhizocephalum Wedd. Campanulaceae (III). 4 Andes.

Rhizoma galangae, Alpinia officinarum Hance.

Rhizome, an underground creeping stem, usu. thickened, and mono- or sympodial, Acorus, Alismaceae, Anemone, Asparagus, Balanophoraceae. Bambusa, Begonia, Bellis, Cyperaceae, Dioscorea, Equisetum, Eranthis, Gramineae, Iridaceae, Juncaceae, Lamium, Liliaceae, Musa, Ophioglossaceae, Petasites, Pteris, Ranunculaceae, Typha, Zingiber.

Rhizophora L. Rhizophoraceae. 3, R. Mangle L. in Am., R. mucronata Lam. and another, Japan to S. Afr. These mangroves (q.v.) are moderate-sized trees with a great development of roots from the stem and branches. On the sub-aerial parts of the roots are large lenticels, probably serving in the same way as the aerenchyma of Bruguiera, &c. The seed germinates upon the tree, the hypocotyl projects at the micropyle and grows rapidly. The bark is used for tanning, yielding a substance known as cutch (cf. Acacia).

Rhizophoraceae ($\overline{E}P$., BH.). Dicots. (Archichl. Myrtiflorae; Myrtales BH.). 12 gen., 60 sp., trop., mostly Old World. See Mangroves. Trees usu. with opp. stip. 1.; fls. sol. or in cymes, &c., \(\frac{1}{2}\), hypoto epi-gynous, reg. K usu. 4-8; C 4-8; A 8-∞, inserted on outer edge of perig. or epig. disc; G (2-5), 2-5-loc. with usu. 2 anatr. pend. ov. in each loc. Fr. a slightly soft berry. Chief genera: Rhizophora, Bruguiera, Weihea.

Rhodamnia Jack. Myrtaceae (1). 12 Malay Penins. to N.S. Wales.

Rhodanthe Lindl. = Helipterum DC. p.p. (Comp.).

Rhodax Spach = Helianthemum Tourn. (Cist.). Rhodea Endl. = Rohdea Roth. (Lili.). 2 China, Japan.

Rosa Tourn. ex L. Rosaceae (III 6). 150 N. temp. and on trop. mts.; 6 in Brit., incl. R. canina L., the dog-rose. The thorns are epidermal appendages. The fl. of R. canina is a pollen fl. The fr. (hip) consists of a number of achenes enclosed in the fleshy recept. which closes over them after fert. R. centifolia L. is the form from which the cabbage rose is derived; and numerous forms of this and other sp. are cult. (see Nat. Pfl.). Otto of rose is distilled mainly from R. damascena Mill., cult. in the Balkans. [E. Willmot, The genus Rosa, London 1914; Baker, Revised Classification of Roses in Journ. Linn. Soc. 35, 1905, p. 70.]

Rosaceae (EP.; BH. incl. Eucryphiaceae). Dicots. (Archichl. Rosales). 100 gen., 2000 sp., cosmop. Trees, shrubs and herbs, usu perenn.;

1. alt. (exc. Rhodotypos), simple or cpd., usu. stip., the stipules often adnate to the petiole. Veg. repr. in various ways, but esp. by creeping stems—runners as in strawberry, or suckers as in raspberry. Fls. term., in racemose or cymose intls. of various types; great variety of forms. Receptacle generally ± hollowed, so that various degrees of perigyny occur. Frequently there is a central protuberance bearing the cpls., even in the forms with very much hollowed recept. In a few cases (subfams, II, IV) the cpls. are united to the recept, and fully inf. The recept. often forms a part of the fr. Fl. usu. and actinom. K 5, often with an epicalyx of outer and smaller I. (see Potentilla),

Floral Diagram of Potentilla fruticosa (after Eichler).
ep. = epicalyx, st. = stipules of bracts and bracteoles.

usu. imbr.; C 5, usu. imbr.; A 2, 3 or 4 times as many as petals, or ∞ , bent inwards in bud; G usu. apocarpous and sup., rarely syncarpous or inf.; cpls. as many or 2 or 3 times as many as petals, or ∞ or 1—4. Ovules anatr., usu. 2 in each cpl. Style often lat. or basal. Fr. various, dry or fleshy; often an aggregate of achenes (Potentilla) or drupes (Rubus), or a single drupe (Piunus), or pome (Pyrus), and so on (cf. genera, esp. those mentioned, and Fragaria, Geum, Rosa, Poterium). Seed usu. exalbum.

Fls. in general of simple type, with slightly concealed honey and

o sta., usu. protandrous. Poterium sp. are anemoph.

Few are of economic value (see Pyrus, Rubus, Fragaria, Prunus),

but many are favourites as garden plants and shrubs.

Classification and chief genera (after Focke). Closely related to Saxifragaceae, some genera being almost arbitrarily placed in one or the other; also nearly allied to Calycanthaceae, Combretaceae, Myrtaceae (floral diagram of M. practically the same as that of § II), Thymelaeaceae, and Leguminosae (through § VI).

 SPIRAEOIDE IE (cpls. 12-1, usu. 5-2, whorled, neither on special carpophore nor sunk in recept., with 2 or more ovules in each; fr. usu. dehisc.; sta. on broad base, tapering

upwards; stipules often absent):

Spiraeeae (follicle, seeds not winged): Spiraea.
 Quillajeae (follicle, seeds winged): Quillaja.
 Holodiscene (achene): Holodiscus (only genus).

II. POMOIDEAE (cpls. 5—2, united to inner wall of recept., usually syncarpous; axis fleshy in fruit, stipules):

Pomaricae: Pyrus.

III. ROSOIDEAE (cpls. ∞ or rarely 1 on carpophore, sometimes

enclosed in axis in fr.; fr. 1-seeded indeh.):

Kerrieae (stips. distinct; axis not forming part of fr.; statapering upwards from broad base; cpls. few, whorled; sta. ∞): Rhodotypos, Kerria.

. Potentilleae (as 5, but cpls. usu. ∞, in a head, or rarely few

and then sta. also few):

2 a. Rubinae (drupes, no epicalyx): Rubus.

2 b. Potentillinae (achenes; seed pend.; usu. epicalyx): Fragaria, Potentilla.

2 c. Dryadinae (as b, but seed erect): Geum, Dryas.

3. Cercocarpeae (stipules slightly developed; torus tubular; cpl. 1; achene): Adenostoma, Purshia.

4. Ulmarieae (torus flat or nearly so; sta. with narrow base):

Ulmaria.

- 5. Sanguisorbeae (torus cup-like enclosing cpls., hardening in fr.; cpls. 2 or more): Alchemilla, Agrimonia, Poterium.
- Roseae (torus cup-like or tubular, enclosing ∞ cpls., and fleshy in fr.): Rosa.
- IV. NEURADOIDEAE (cpls. (5—10) united to torus, which is dry in fr.; herbs).
 - Neuradeae: Neurada.

 V. PRUNOIDEAE (cpl. 1, rarely 2—5, free of torus; drupe; trees with simplel.; style almost term.; ovules pend.; fls.reg.).

 Pruneae: Nuttallia, Prunus.
- VI. CHRYSOBALANOIDEAE (as V, but style basal and ovules erect):

1 a. Chrysobalaninae (nearly reg.): Chrysobalanus.

I b. Hirtellinae (zygomorphic): Hirtella.

Rubens (Lat.), blush-red.

Rubeola Tourn, ex Adans. = Crucianella L. (Rubi.).

Ruber (Lat.), red.

Rubia (Tourn.) L. Rubiaceae (II. II). 15 Eur., As., Am. (I in Brit.). R. tinctorum L. is the madder, formerly cult. for its dye (alizarin),

which is now prepared artificially.

Rubiaceae (EP., BH.). Dicots. (Sympet. Rubiales). 450 gen., 5500 sp., one of the largest fams. of pl. Most are trop., but a number (esp. Galicae) are temp., and Galium itself has a few arctic sp. Trees, shrubs and herbs with decussate stip, entire or rarely toothed 1. The stips. exhibit great variety of form; they stand either between the petioles (interpetiolar) or between the petiole and the axis (intrapetiolar), and are frequently united to one another and to the petioles, so that a sheath is formed round the stem. The two stips.—one from each l.—that stand side by side are usu. united, and in the Galieae, to which the Brit. sp. belong, are leaf-like, and often as large as the ordinary l.; a char. appearance is thus produced, the plants seeming to have whorls of l.; and it is only by noting the axillary buds that a clue is obtained to the real state of affairs. The number of organs—l. and stips.—in a whorl varies from 4 upwards, according to the amount of 'fusion' or 'branching' of the stips. The simplest case is a whorl of 6, each leaf having 2 separate stips.; if the stips. be united in pairs, a whorl of 4 results; if each stip. be branched into two, we get a whorl of 10, and, if the centre pair of half-stips. on either side be united, a whorl of 8.

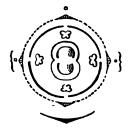

Several are myrmecophilous (cf. Cecropia, Acacia), e.g. Myrme-

codia, Cuviera, Duroia, Hydnophytum.

Infl. typically cymose. Sol. term. fls. rare; small dichasia more frequent; most common case a much branched

cymose panicle.

Fl. usu. §, reg., epig., 4- or 5-merous. K 4.—5, epig., often almost absent, usu. open in aestivation, sometimes with one sepal larger than the rest and brightly coloured (Mussaenda, &c.); C (4—5), valvate, conv., or imbr.; A 4—5, alt. with petals, epipet.; G (2) rarely (1—∞), 2-loc. with 1—∞ anatr. ov. in each loc.; ov. erect, pend., or

Floral diagram of Asperula, after Eichler.

horiz.; style simple; stigma capitate or lobed. Caps. (septi-loculi-cidal), berry or schizocarp. Embryo small, in rich endosp.

Most have conspice insect-pollinated fis. The Brit. sp. have small fis. with freely exposed or slightly concealed honey, chiefly visited by flies; many trop. sp. have been and Lepidoptera fis. with long tubes. Honey usu, secreted by an epig, nectary round base of style. Heterostylism is common, and dioecism sometimes occurs.

Several are of economic importance, e.g. Cinchona, which yields quinine, while many of its allies have also valuable alkaloids, Coffea

(coffee), Uragoga (ipecacuanha), Rubia, &c.

Classification and chief genera (after Schumann). The R. are closely allied to Caprifoliaceae (q.v.) and less nearly to Compositae, &c. I. CINCHONOIDEAE (ovules ∞ in each loculus).

A. CINCHONINAE (fruit dry):

a. Fls. solitary or in decussate panicles.

a. Fl. regular; seed not winged; C valvate.

1. Condaminecae : Condaminea.

Oldenlandieas: Oldenlandia, Houstonia, Pentas.
 As a, but C imbr. or conv.

3. Rondeletieae : Rondeletia.

c. As a, but C 2-lipped.

4. Henriquezieae: Henriquezia. d. As b, but seed winged.

5. Cinchoneae: Cinchona, Bouvardia, Cosmibuena.

β. Fls. in heads.

6. Naucleeae: Uncaria, Nauclea.

B. GARDENINAE (fruit fleshy):

7. Mussaendeae (C valvate): Mussaenda.

8. Gardenieae (Cimbr. or conv.): Randia, Gardenia, Posoqueria, Duroia.

II. COFFEOIDEAE (ovules 1 in each loculus).

A. GUETTARDINAE (ovule pendulous; micropyle facing upwards):

1. Vanguerieae: Plectronia, Cuviera.

2. Guettardeae: Guettarda.

3. Chiococceae: Chiococca.

B. PSYCHOTRIINAE (ovule ascending; micropyle facing downwards):

a. C convolute.

4. Ixoreae: Coffea, Ixora, Pavetta.

B. C valvate.

a. Ovules inserted at base of loculus.

5. Psychotricae: Psychotria, Rudgea, Uragoga, Lasianthus, Myrmecodia.

6. Paederieae: Paederia.

7. Anthospermeae: Nertera, Coprosma, Mitchella.

3. Coussareeae: Faramea.

b. Ovules on septum.

- Morindeae (stip. undivided, not leasy; trees and shrubs): Morinda.
- 10. Spermacoceae (stip. divided; shrubs and undershrubs): Borreria.

11. Galicae (stip. leafy; herbs): Sherardia, Crucianella, Asperula, Galium, Rubia.

Rubiales. The 8th order (EP.) of Sympetalae. The 1st (BH.) of Gamopetalae. The 8th (Warming) of Sympetalae.

Rubiginose, rust-coloured.

Rubus (Tourn.) L. Rosaceae (III. 2 a). 225 cosmop., esp. N. temp. (5 or 6 in Brit.). Fls. conspic.; honey secreted by a ring-shaped nectary upon the hollowed axis just within the insertion of the sta. Fls. homogamous, visited by many insects, including bees. Fr. an aggregate of drupes. R. Chamaemorus L., the cloudberry (arctic. Scotland), has creeping underground stems by means of which a large veg. repr. is carried on. Fls. sol., term. and unisexual, occasionally \$. R. Idaeus L. (raspberry) multiplies largely by suckers -stems which grow out horiz. beneath the soil to some distance, then turn up and give rise to new pl. which flower in their second R. fruticosus L. (a general specific name for the o var. of the common bramble or blackberry) is a hook-climber (the hooks being emergences) sprawling over the surrounding vegetation. Branches which reach the soil often take root there and grow up into new plants. R. caesius L. (dewberry) has fr. covered with bloom (wax) like grapes. R. occidentalis L. is the black-cap raspberry or trimbleberry of N. Am. R. australis Forst. f. has the blades of the leaves reduced to the minimum. Many sp. and vars. of blackberry, rasp-

berry, &c. are cult. ed. fr. The loganberry, a form which appeared in 1881 in the grounds of Judge Logan at Santa Cruz, Calif., is usu. supposed to be a hybrid, but this is disputed. See Journ. of Hered. Nov. 1916, p. 504.

Rusbyella Rolfe. Orchidaceae (II. 19). 1 Bolivia.

Ruscus (Tourn.) L. Liliaceae (VII). 3 Medit., Eur. R. aculeatus L., butcher's broom, in Brit., a small shrub. In the axils of scaly 1. stand leaf-like phylloclades; half-way up each is another scaly l., in whose axil stands the fl. Berry. [Cf. Asparagus and Semele.]
Rush, Juncus; beak-, Rhynchospora; bul-, Typha; Dutch-, Equi-

setum; flowering -, Butomus; - grass (Am.), Sporobolus; spike -, Eleocharis; wood -, Luzula.

Ruspolia Lindau. Acanthaceae (IV. B). 2 Somaliland.

Russelia Jacq. Scrophulariaceae (II. 4). 8 trop. Am. R. juncea Zucc., often cult., is xero. with much reduced 1. and pendulous green stems. Shoots sometimes appear under cult. with broad 1. (perhaps a reversion to an ancestral type).

Russian thistle, Salsola Kali, L., var. tragus Moq.

Russowia C. Winkler. Compositae (11). 1 Turkestan.

Rust, Berberis, Triticum.

Rustia Klotzsch. Rubiaceae (1. 1). 6 trop. Am.
Ruta (Tourn.) L. Rutaceae (1). 50 Medit., As. R. graveolens L., rue, cult., is a strongly smelling shrub, owing to the presence in the 1., &c., of an ethereal oil. The terminal fl. of the infl. is 5-merous, the lat. fls. 4-merous. The sta. lie in pairs in the boat-like petals; one by one they bend upwards over the stigma, dehisce and fall back; when all have done this, the stigma ripens, and finally the sta. again move up and effect self-fert. Chiefly visited by small flies. Rue is a narcotic and stimulant.

Rutabaga, Brassica campestris L.

Rutaceae (EP., BH. add § 11 to Meliaceae). Dicots. (Archichl. Geraniales). 100 gen., with 800 sp. trop. and temp., esp. S. Afr. and Austr. Most are shrubs and trees, often xero., frequently of heathlike habit (e.g. Diosma). L. alt. or opp., exstip., usu. cpd., with

В

Floral diagrams of Rutaceae, after Eichler. A, Ruta graveoleus (d = disc); B, Citrus Aurantium, single case showing variable numbers in stamen-bundles.

glandular dots, often aromatic. In many Aurantieae there are short shoots whose I. are reduced to thorns (cf. Cactaceae). Infl. of various forms, usu. cymose. Fl. &, rarely unisexual, reg. or +, 5-4-merous (see Ruta), with a large disc below G. K or (K) 5 or 4, odd sepal post.; C 5 or 4 imbr.; A 10 or 8, obdiplost or 5, 3, 2, or ∞ , with intr. anthers; G (5 or 4), rarely (3—1) or (∞), often free at base and united above by the style (c/. Apocyn.), multiloc.; ov. 2— ∞ or 1 in each loc., anatr. with ventral raphe and micropyle facing upwards. Fr. various; schizocarps, drupes, berries, &c. Seeds with or without endosp.

Several R. are or have been used in medicine, chiefly on account of the oils they contain, e.g. Ruta, Galipea, Toddalia, &c. Citrus yields important fruits (orange, &c.), and Chloroxylon a timber.

Classification and chief genera (after Engler): The groups of R. differ considerably among themselves, and several of them were formerly regarded as independent fams. The relationships to allied fams. are thus given by Engler:

Zygophyllaceae Cneoraceae Simaiubaceae (Simaiubaceae

I. RUTOIDEAE. Cpls. usu. 4-5, rarely 3-1, or > 5, often only united by the style, and \pm divided when ripe; loculic. dehiscence usu. with separation of the endocarp; rarely 4-1 fleshy drupes.

1. Zanthoxyleae (woody plants, usu. with small greenish, reg., often unisexual fls.; cpl. rarely with > 2 ovules; embryo with flat cots. in endosp.): Zanthoxylum, Fagara, Choisya.

cots. in endosp.): Zanthoxylum, Fagara, Choisya.
2. Ruteae (herbs or undershiubs, rarely shrubs, with moderate

2. Ruteae (neros or underships, rarely shrubs, with moderate sized § fls., sometimes slightly +; cpls. usu. with > 2 ov.; endosp.): Ruta, Dictamnus.

3. Boronicae (undershrubs and shrubs, with reg. usu. § fls.; endosp. fleshy, otherwise as 2): Boronia, Eriostemon, Conea.

4. Diosmeae (undershrubs and shrubs, rarely trees with simple 1.; exalbum., embryo usu. straight with fleshy cots.): Calodendron, Adenandra, Diosma.

5. Cusparieae (shrubs and trees with reg. or 4 fls.; endosp. little or 0; embryo curved, with radicle between the cots.): Almeidea, Galipea, Cusparia.

6. Dictyolomeae (fis. reg., haplostemonous; sta. with scales at base; cpls. with ∞ ovules, only united at the base; trees with double pinnate 1.): Dictyoloma.

II. FLINDERSIOIDEAE. Cpls. (5-3), each with 2-8 2-ranked erect ovules; capsule loculic. or septic. with persistent endocarp; seed winged, exalbum. woody plants with lysigenous glands.

Flindersieae: Flindersia, Chloroxylon.

III. SPATHELIOIDEAE. Cpls. (3) each with 2 pend. ov.; drupe winged; secretory cells and lysigenous oil-glands at margins of L.

Spathelieae: Spathelia.

IV. TODDALIOIDEAE. Cpls. (5—2) or 1, each with 2—1 ov.; drupe or dry winged fr.; endosp. or o; l. and bark with lysigenous oil-glands.

Toddalieae: Ptelea, Toddalia, Skimmia.

V. AURANTIOIDEAE. Berry, often with periderm, and

with pulp derived from sappy emergences of cpl. wall. Seeds exalbum., often with 2 or more embryos. Lysigenous oil-glands. Aurantieae: Glycosmis, Limonia, Atalantia, Feronia, Aegle, Citrus. Ruthea Bolle (Lichtensteinia BH.). Umbelliserae (III. 5). 2 Canaries. Rutidea DC. Rubiaceae (II. 4). 15 trop. Afr., Madag. | St Helena. **Butidosis** DC. Compositae (4). 6 Austr. Saccardophytum Spegazzini. Solanaceae (inc. sed.). 1 Patagonia.

Saccellium Humb. et Bonpl. Boraginaceae (11). 1 Peru, Argentina. Saccharodendron Nieuwland (Acer p.p.). Aceraceae. 5 N. Am. Saccharum L. Gramineae (2). 12 trop., subtrop., incl. S. officinarum L. (sugar cane), a native (?) of trop. E. As., now cult. in most warm regions, esp. Java, Hawaii, U.S., &c. From the rhiz. there spring each year shoots which may reach 12-15 feet and a thickness of 2 inches: the outer tissues have much silica in their cell-walls. The infl. is a dense woolly spike, the first and second glumes of each spikelet being covered with long hairs. The cult. form has always been veg. propagated (pieces of the haulm, each bearing a bud, are planted), but recently a more vigorous race has been raised from seed. The sugar is contained in the soft central tissues of the stem; the canes are cut before flowering and crushed between rollers to extract the juice; afterwards it is boiled down under reduced pressure and laid out to crystallise.

Saccocalyx Coss. et Dur. (Satureia p.p. BH.). Labiat. (VI). 1 Alger. Saccoglossum Schlechter. Orchidaceae (II. 16). 2 New Guinea. Saccoglottis Endl. Humiriaceae. 10 trop. S. Am., Afr.

Saccolabium Blume. Orchidaceae (II. 20). 50 Indomal. Cult. orn. fl. Saccolaria Kuhlmann. Lentibulariaceae. I Upper Amazon.

Saffordia Maxon. Polypodiaceae. 1 Peru.

Saffordiella Merrill (Leptospermum p.p.). Myrt. (II. I). I Phil. Is. Saffranhout, Elacodendron croceum DC.

Saffron, Crocus sativus L.; meadow -, Colchicum autumnale L.

Sage, Salvia, esp. S. officinalis L.; - brush, Artemisia tridentata Nutt., &c.; -rose (W.I.), Turnera; wood -, Teucrium.

Sageraea Dalzell (Bocagea BH.). Anonaceae (1). 6 Indomal.

Sageretia Brongn. Rhamnaceae. 12 warm E. As., N. Am. Sagina L. Caryophyllaceae (I. 1). 20 N. temp.; 4 in Brit. (pearl-

wort). Small herbs with inconspic., sometimes apet. fis.

Sagittaria Rupp. ex L. Alismaceae. 33 Am., temp. . , incl. S. sagit-tifolia L. (arrow-head) in Eur. (incl. Brit.), a water-plant with a short rhiz. bearing 1. of various types, the number of each kind depending on the depth of the water, &c. The fully submerged 1. are ribbonshaped, the floating ones have an ovate blade, whilst those (usually the majority) that project above water are arrow-shaped (sagittate). In the axils are formed the 'renewal' shoots which last over the winter, short branches which burrow into the mud and swell up at the ends each into a large bud whose central axis is swollen with reserve-materials; in spring this develops into a new plant. The diclinous racemose infl. projects above water; the $\mathfrak F$ fis. are lower down than the $\mathfrak F$. The $\mathfrak F$ contains ∞ sta., the $\mathfrak F$ ∞ cpls.

Sagittate (l.), with two lobes at base projecting towards stem.

Sagittipetalum Merrill. Rhizophoraceae. 2 Phil. Is.

Sago, Metroxylon, and Arenga, Caryota, Cycas, Oreodoxa, &c.

Sagotanthus Van Tiegh. (Heisteria p.p.). Olacaceae. 1 Guiana.

Sagotia Baill. Euphorbiaceae (A. II. 5). I N. Brazil, Guiana.

Sagraea DC. (Clidemia p.p. EP.). Melastomaceae (1). 20 trop. Am. Saguerus Adans. = Arenga Labill. (Palm.).

Sagus Rumph ex Gaertn. = Metroxylon Rottb. (Palm.).

Sahagunia Liebm. (Acanthinophyllum Allem.). Moraceae (II). 3 trop. Am. S. strepitans Engl. (Braz.), good timber.

Sails, cf. Bamboos.

Bainfoin, Onobrychis sativa Lam.

St Dabeoc's heath, Daboecia; - Ignatius' beans, Strychnos Ignatii Berg.;

- John's bread, Ceratonia; -- wort, Hypericum.

Saintpaulia H. Wendl. Gesneriaceae (i). 3 E. Afr., incl. S. ionantha H. Wendl. (Afr. violet). The fl. is like that of Exacum, with similar dimorphic symmetry. In some the style projects to the left over the C, in others to the right (cf. Exacum, Cassia).

Sakersia Hook. f. Melastomaceae (I). 2 Cameroons.

Bal, Shorea robusta Gaertn. f.

Salacia L. Hippocrateaceae. 100 trop., often lianes with dimorphic branches, one form suited for climbing.

Salacicratea Loes. Hippocrateaceae. 1 New Guinea.

Salacistis Reichb. f. (Helaeria BH.). Orchidaceae (II. 2). I Java.

Balad oil, nominally olive oil, Olea europea L.

Salaxis Salisb. Ericaceae (IV. 2). 24 Cape Colony.

Salazaria Torr. Labiatae (IV). I S.W. U.S., Mexico.

Saldanhaea Bur. Bignoniaceae (1). 2 Brazil.

Saldania Sim. Leguminosae (III. 8). I S.E. Afr.

Saldinia A. Rich. Rubiaceae (II. 5). 2 Madag.

Salep, the dried tubers of some sp. of Orchis and (in India) Eulo-

phia.

Salicaceae (EP., BH.). Dicots. (Archichl. Salicales; anom. Incompletae BH.). 2 gen., 180 sp., N. temp., trop. and subtrop. Shrubs or trees with stip. l. and much veg. repr. by suckers. Fls. naked, in catkins or spikes, dioec. (many hybrids exist). The catkins arise in autumn and remain as buds through the winter, developing in early spring. The \$\sigma\$ fl. consists of \$2\theredowngapeq 30 sta. in the axil of a bract, the \$\gamma\$ usu. of (2) cpls. transv. placed, syncarpous with parietal plac.; ovules \$\infty\$, anatr. Seeds exalbum. with basal tufts of hairs. Genera: Salix, Populus.

Salicales. The 3rd order of Archichlamydeae.

Salicaria Tourn. ex Mill. = Lythrum L. (Lythr.).

Salicifiorae (Warming). The 1st order of Choripetalae.

Saltornia (Tourn.) L. Chenopodiaceae (A). 10 on sea-coasts. S. herbacea L. (saltwort) cosmop., incl. Brit. Succulent herbs, with the habit of a cactus, leafless and with jointed nodes. Fls. in groups of 3

or more, one group sunk in the tissue on either side of each internode. P fleshy; sta. 1 or 2.

Salisburia Sm. = Ginkgo L. (Ginkg.).

Salix (Tourn.) L. Salicaceae. 160 cosmop. The sp. are difficult to separate and there are many hybrids (cf. Rubus, Rosa). 12 in Brit. (willow, sallow, &c.). Branching monopodial, but the term. bud usudies, and the next lat. bud continues the axis. Some have collateral buds in the axils. There is extensive veg. repr. by suckers. Some, e.g. S. alba L., are often pollarded, or cut off at a height of 8 feet or so; from the callus formed upon the wounds new shoots spring, and thus the 'crown' of shoots is produced. Among the Brit. sp. are S. herbacea L., the dwarf or arctic willow, a creeping alpine and arctic form, and S. lanata L., &c. alpine forms with very woolly l. The fls. contain honey, and as they appear in early spring, before the l., and when they have but few competitors, they receive a great many visits from insects, especially from bees. S. viminalis L. is the osier, whose twigs are used in making baskets, &c. S. babylonica L. is the weeping willow. S. caprea L. useful wood.

Sallal, Gaultheria Shallon Pursh.

Sallow, Salix.

Salmea DC. Compositae (5). 12 Mexico, W.I.

Salmeopsis Benth. Compositae (5). 1 S. Brazil, Paraguay.

Salvador tea, Gaultheria.

Salvadora Garcin. ex L. Salvadoraceae. 2 W. As., Afr. S. persica L. is said to be the mustard of the Bible. Its l. taste like mustard.

Salvadoraceae (EP., BH.). Dicots. (Archichl. Sapind.; Gentianales BH.). 3 gen., 8 sp., As., Afr. Shrubs and trees with opp. entire stip. 1. and racemose infls. Fls. § or unisexual, reg. K (2-4); C 4-5 or (4-5), usus with teeth or glands on inner side; A 4-5, epipet. or not; G (2), 1-2-loc, with 1-2 erect anatr. ov. in each.

Fr. a 1-seeded berry or drupe. Seed exalbum. Genera: Azima, Dobera, Salvadora. The relationships are doubtful, for we do not know if the polypetaly of A. and D. is original or secondary.

Salver-shaped (C), ± flat, with long tubular portion, *Primula*.

Salvertia A. St Hil. Vochys. I campos of S. Brazil. Stigma lat.

salvertia A. St Hil. Vochys. I campos of S. Brazil. Stigma lat salvetia Pohl. Inc. sed. Nomen.

Salvia (Tourn.) L. Labiatae (v1). 550 trop. and temp. S. Verbenaca L. (sage) and S. pratensis L. (clary) in Brit. The sta. are reduced to 2 (the ant.), each of which has a sort of T-shape, the connective of the versatile anther being greatly elongated. The stalks of the sta. stand up together across the mouth of the fl., and a bee, in pushing down towards the honey, comes into contact with the inner end of the anther, and raising it causes the outer to descend upon its back and to rub it with pollen. In some forms of S. both ends of the leven bear feetile anthers; but in most the useless half-anther at the inner end is aborted, and the outer half of the connective is much longer than the inner (compare S. officinalis with S. pratensis). The fl. is protandrous, and in the later stage the style bends down and places the stigma in position to be touched first by an entering insect. Some have coloured bracts at the top of the infl., adding to its conspicuousness. S. officinalis L. (Medit.) is the garden sage.

Salviacanthus Lindau. Acanthaceae (IV. B). 1 Cameroons. Salviastrum Scheele. Labiatae (VI). 3 Texas, New Mexico.

Salvinia (Mich.) Schreb. Salviniaceae. 10 trop. and warm temp., incl. S. natans (L.) All. The pl. floats freely on the water; at each node is a whorl of three l., and the whoils alt. with one another. There are two floating l. derived from the upper half of a segment of the apical cell (see fam.), and a submerged l. derived from the lower. There are no 100ts, their function being performed by the finely divided submerged l. (cf. Trapa, Ranunculus, Cabomba). The sporocarps are boine several together as outgrowths from the base of a submerged l. The microspores germinate inside the sporangium, the prothalli emerging through its wall as fine tubes, at the end of which the antheridia form.

Salviniaceae. Filicales Leptosporangiatae. Two genera, Salvinia (l. in whorls of 3) and Azolla (l. in two ranks), with 15 sp., trop. and temp. Water plants, with a stem floating upon the water, and growing by a two-sided apical cell (3-sided in the young embryo, as in other Filicales). A dorsiventral construction thus arises; segments are cut off right and left from the apical cell, and the first division of each of these segments divides it into a dorsal and a ventral half. In S. the dorsal halves give rise to the floating, the ventral to the submerged l.; in A. the former give rise to the l., the latter to the branches and roots. The sporangia are grouped into sori; the sorus is enclosed in a highly developed indusium, forming a sporocarp. Each contains only one kind of sporangium (micro- or mega-sporangia). The sporocarp is an outgrowth of a 1.,-in S. of a submerged 1., in A. of the ventral lobe of an ordinary 1. The spore is covered with an epispore, consisting of hardened frothy mucilage. It sinks, when set free from the sporangium. On germ. the microspore forms a rudimentary o prothallus consisting of one (?more) veg. cell and an antheridium. The megaspore forms a ? prothallus, which remains enclosed in the burst spore, and has two parts, an upper small-celled green part on which are borne the archegonia, and a lower colourless part (of one or more large cells), in which reserves are stored up for the use of the young plant which will be formed from a fert. ovum (cf. Selaginella and Phanerogams).

Salzmannia DC. Rubiaceae (II. 3). I E. Brazil.

Samadera Gaertn. Simarubaceae. 7 Madag., Indomal.

Saman, Pithecolobium Saman Benth.

Samara L. = Embelia Burm. p.p. (Myrsin.).

Samara, a winged 1-seeded indeh. achene or nut, Acer, Banisteria, Fraxinus, Liriodendron, Ptelea, Pterocarpus, Ulmus, Ventilago.

Sambucus (Tourn.) L. Caprifoliaceae. 20 N. temp., S. Am., As. to Austr. S. nigra L. (elder) and S. Ebulus L. in Brit. Differs from the rest of the fam. in having cpd. 1. and extr. anthers; it also possesses well-marked stipules. Lenticels show clearly in the bark. S. nigra L. shows serial adv. buds. There has been some discussion about the proper position to be assigned to it; it has been put in Valerianaceae or in a new family, Sambucaceae, forming a link between Rubiales and Aggregatae. A wine is prepared from elder berries.

Sameraria Desv. (Isatis BH.). Cruciferae (2). 7 E. Medit.

Samoa millet, Panicum.

Samolus (Tourn.) L. Primulaceae. 10 cosmop., esp. **; S. Valerandi L. (brook-weed) in Brit. The whole pl. dies down in autumn, but young shoots form in summer and take root. The bracts of the fls. are 'adnate' to the axes, so as to look like sol. bracteoles (cf. Solanaceae).

Sanicula (Tourn.) L. Umbelliferae (II. 1). 40 cosmop. exc. Austr. S. europaea L. (sanicle) in Brit. Fls. in cymose umbels, themselves

arranged in dichasia. Fr. hooked, animal distributed.

Sansevieria Thumb. Liliaceae (VIII). 60 trop. Afr., As. Xero. with

fleshy 1. S. zeylanica Willd. yields fibre (bow-string hemp).

Santalaceae (EP.; BH. incl. Grubbiaceae, Myzodendraceae). Dicots. (Archichl. Santalales; Achlamydosporeae BH.). 26 gen., 250 sp., of semi-parasitic shrubs, trees and herbs, resembling Loranthaceae in many ways, trop. and temp. Some are stem-parasites like mistletoe. others root-parasites like Rhinanthus (e.g. Thesium). L. opp. The total infl. may be a raceme, spike, head, &c., but often, instead of the single fl. in each axil, there is a little cyme of 3, as in Loranthaceae. Fls. For unisexual, with perig. or epig. disc and a simple P (sepaloid or petaloid); sta. =, and inserted on, the P-leaves. G 1-loc., with a central placenta bearing 1-3 ovules. Nut or drupe; seed 1, with no testa, and much endosp. Chief genera: Santalum, Thesium.

Santalales. The 14th order of Archichlamydeae. Cf. p. xii.

Santalina Baill. Rubiaceae (1. 8). 1 Madag.

Santalodes O. Ktze., Santaloides Schellenb. = Rourea Aubl. p.p.

Santalum L. Santalaceae. 10 Indomal. Parasitic trees. S. album L. (S. Ind., esp. Mysore) furnishes the true sandal-wood (yellow or white). Oil is distilled from it.

Santiria Blume. Burseraceae. 30 Malaya.

Santiridium Pierre = Pachylobus G. Don p.p. (Burser.).

Santiriopsis Engl. (Santiria p.p.). Burseraceae. 1 S. Thome.

Santolina Tourn. ex L. Compositae (7). 8 South Eur. S. Chamaecyparissus L. is officinal.

Sanvitalia Gualt. in Lam. Compositae (5). 8 warm Am. Cult. orn. fl. Sap-green, Rhamnus cathartica L.; -wood, the young outer wood.

Sapidus (Lat.), with pleasant taste.

Sapindaceae (EP.; BH. incl. Aceraceae, Hippocastanaceae, Melianthaceae, Staphyleaceae). Dicots. (Archichl. Sapindales). 120 gen., 1000 sp., trop. and subtrop. 5 gen. (Serjania, Paullinia, &c.) with 300 sp. are lianes, the rest erect trees or shrubs. The lianes climb by tendrils. which are met. infl.-axes and are usu. branched or sometimes watchspring-like; their stems often show peculiar internal anatomy. L. alt., stip. in the climbing sp., usu. cpd., pinnate; in the climbing sp. there is usu. a true term. leaflet, but not in the erect; in these one of the last pair of leaflets often becomes term., so that the l. is asymmetric. The tissues of the plants usually contain resinous or latex-like secretions in special cells. The infl. is cymose, usu. a cincinnus, with bracts and bracteoles.

Fl. unisexual (the sta. are apparently well developed in the ? so that it is easily mistaken for \(\frac{1}{2}\), but the pollen is useless, and the anthers do not open), generally monoec., reg. or often obliquely ..., 5- or 4merous. K usu. 5, rarely (5), imbr. or rarely valvate or open, sometimes apparently 4-merous by union of 2 sepals; C usu. 5, imbr., with well-marked disc between it and the sta.; A usu. 5+5 in one whorl, often with 2 absent, more rarely 5, 4, or ∞ , inserted within or rarely upon the disc round the rudimentary ovary; \underline{G} in \Re fl. usu. (3), 3-loc. with term. style; ovules usu. I in each loc., ascending, with ventral raphe. Fr. a caps., nut, berry, drupe, schizocaip, or samara, usu. large, often red; seed often arillate, with no endosp.; embryo usu. curved.

Many S. are of economic value; several yield valuable timber;

Nephelium, Litchi, and others furnish ed. fr.

Classification and chief genera (after Radlkofer):

 EUSAPINDACEAE (ov. sol. in loc., erect or ascending, micropyle down): Serjania, Paullinia, Sapindus, Talisia, Schleichera, Litchi, Nephelium, Pappea, Cupania, Blighia.

II. DISSAPINDACEAE (ov. usu. 2 or several in each loc., in the first case erect or pend., in the second horiz., rarely 1 pend. with micropyle up): Koelreuteria, Dodonaea.

Sapindales. The 24th order (EP.) of Archichlamydeae. The 10th

(BH.) of Polypetalae. Cf. pp. xxvi, li.

Sapindus Tourn. ex L. Sapindaceae (1). 20 trop. and subtrop. exc. Afr. and Austr. The berries of S. Saponaria L. (Am.) contain

saponin, form a lather with water, and may be used as soap.

Sapium P. Br. Euphorbiaceae (A. II. 7). 100 warm. Seeds of S. sebiferum Roxb. (tallow-tree, China) are coated with fat; they also yield an oil by pressure. Some yield rubber (Bolivian, Colombian).
 Sapodilla plum, Achras Sapota L.

Saponaria L. Caryophyllaceae (II. 2). 20 N. temp., chiefly Medit. S. officinalis L. (soapwort) in Brit. Its leaves lather if rubbed with

water. Fls. protandrous, butterfly-visited.

Saponin, Chlorogalum, Gouania, Limonia, Sapindus, Saponaria.

Sapota Plum. ex Mill. = Achras L. (Sapot.).

Sapotaceae (EP., BII.). Dicots. (Sympet. Ebenales). 35 gen., 600 sp., trop., mostly trees with entire leathery 1., sometimes stip. They are commonly hairy with 2-shanked hairs, and contain secretory passages in pith, cortex and 1. Fls. sol. or in cymose bunches in the 1. axils or on old stems, bracteolate, \(\frac{1}{2}\), reg. or not. K 2+2, 3+3, 4+4, or 5; C asu. equal in number to sepals, and alt. with the K as a whole, as in Cruciferae, rarely in 2 whorls. In Minusopeae the petals have dorsal appendages like themselves, giving the appearance of more than one whorl. Sta. in 2 or 3 whorls, but frequently the outer staminodial or absent; anthers commonly extr. \(\frac{C}{2}\), syncarpous, multiloc.; cpls. = or twice the number of sta. in a whorl, or more; ovules at base of axile placenta, one in each loc., anatr. with micropyle facing down; style simple. Berry, the flesh sometimes sclerenchymatous near the surface. Seeds few or one, usually album.; endosp. oily; testa hard and rich in tannin.

Many S. furnish useful products, esp. gutta-percha and balata;

see all genera below. A fam. of conspic. economic value.

Classification and chief genera (after Engler):

I. Palaquieae (petals without appendages): Bassia, Payena, Palaquium, Achras, Butyrospermum, Sideroxylon, Chrysophyllum.

II. Mimusopeae (petals with appendages—see above): Mimusops.

Sapote, Lucuma mammosa Gaertn. f.

Sappan wood, Caesalpinia sappan L. Sapranthus Seem. (Porcelia BH., Uvaria p.p. EP.). Anon. (1). I C. Am. Sapria Griff. Rafflesiaceae. I Assam. Saprophytes, plants which grow upon decaying organic matter and absorb the products of decay, Burmanniaceae, some Gentianaceae (Bartonia, Obolaria, &c.), Monotropa, some Orchidaceae (Corallorhiza, Epipogon, Limodorum, Neottia, &c.), Triuridaceae, the prothallus of Ophioglossaceae. Saprosma Blume. Rubiaceae (II. 5). 20 Indomal. Sapu (Ceylon), Michelia Champaca L. Sapucaia nut, Lecythis. Saraca L. Leguminosae (II. 3). to trop. As. Young shoots pend. (cf. Amherstia, Brownea). Sarracenia L. Sarraceniaceae. 7 Atl. N. Am. (side-saddle fl.), in sunny marshy places. Low herbs with rosettes of rad. l.; each l. is repres. by a long narrow pitcher with a flat green wing of tissue on the ventral side, serving chiefly for assim. The general structure of the pitcher is similar to that found in Nepenthes; it has a fixed lid projecting over the mouth, and the lip is usu. turned down inwards. The mouth bears numerous honey-glands; below these comes the 'slide-zone,' then the zone of hairs (cf. Nepenthes), and at the bottom is water in which the insects are drowned. The pitchers are often brightly coloured. In S. the entire l. is a pitcher, while in Nepenthes it is only part of the l., and in Cephalotus only certain l. Many cult. orn.; many hybrids.

Sarraceniaceae ($\dot{E}P$., BH.). Dicots. (Archichl. Sarraceniales; Parietales BH.). 3 gen., 9 sp., Am. Insectivorous pitcher-plants (see gen.) with rosettes of rad. 1. and ξ reg. fls. K 9—8—5, spiral, if > 5 the outer 3 small; C as many as inner sepals and alt. with them, or o; A ∞ ; \underline{G} (6—5—3) with ∞ anatr. ov. on inrolled cpl.-walls. Loculic caps. with ∞ seeds; endosp. fleshy. Genera: Heliamphora (raceme; ovary 3-loc.), Sarracenia (fl. sol.; ovary 5-loc., the top of the pitcher simple), Darlingtonia (ditto, but the top of the pitcher fish-tail-shaped).

Savoury, Saturcia.

saw wort, Serratula tinctoria L.

Saxatilis (Lat.), growing on rocks.

Saxegothaea Lindl. Coniferae (Taxac. 3; see C. for gen. char.).
 I Andes of Patagonia. Fr. a many-seeded 'berry' like Juniperus.
 Saxifraga Tourn. ex L. Saxifragaceae (I). 325 N. temp., Arctic,

Andes, chiefly alpine. 13 in Brit. (saxifrage). Most show xero. char., such as tufted growth, close packing of I. (esp. well shown in S. oppositifolia L.), succulence, hairiness, &c. Many are veg. repr. by offsets, or (e.g. S. granulata L.) by bulbils in the lower leaf-axils. Many exhibit chalk-glands at the tips or edges of the I. (e.g. S. oppositipolia at the tip); these are water-pores with nectary-like tissue beneath, secreting water containing chalk in solution. As the water evaporates, the chalk forms an incrustation. Fls. usu. in dich. cymes with cincinnus tendency. Every stage occurs from hypogyny to epigyny. Honey only partially concealed; fls. visited by miscellaneous insects. Most are protandrous. A few. e.g. S. sarmentosa Linn. f., have + fls. Saxifragaceae (EP.; BH. incl. Cephalotaceae, Cunoniaceae). Dicots. (Archichl. Rosales). on gen. 750 sp. cosmon. chiefly temp. Most

(Archichl. Rosales). 90 gen., 750 sp. cosmop., chiefly temp. Most are perenn. herbs, a few shrubs or trees, with usu. alt., rarely stip. l. Many alpine and arctic forms of xero. habit. Infl. of various kinds,

both racemose and cymose.

Fl. usu. §, reg., cyclic, 5-merous (exc. cpls.). Recept. flat or hollowed to various depths, so that sta. and P may be peri- or epigynous. K usu. 5; C 5, imbr. or valvate, sometimes (5) or o; A usu. 5+5, obdiplost.; cpls. rarely free and as many as petals, usually fewer and joined below, often 2; plac. parietal or axile, with several rows of anatr. ov.; styles as many as cpls. Fls. mostly protandrous. Capsule or berry. Seed with rich endosp. round a small embryo.

Of little economic importance; Ribes yields valuable tr. Many favourites in horticulture, e.g. Saxifraga, Francoa, Philadelphus,

Deutzia, Hydrangea, Escallonia. Classification and chief genera:

 SAXIFRAGOIDEAE (herbs of various habit; l. alt.; P 5- or rarely 4-merous; G usu. (2), hypo- or epi-gynous, 1- or 2-loc.): Saxifraga, Tellima, Chrysosplenium, Parnassia.

II. FRANCOIDEAE (perenn. herbs with rad. I. and spikes or racemes on naked scapes; fl. 4-merous; G 4-loc.): Francoa.

III. HYDRANGEOIDEAE (shrubs or trees; l. usu. opp., simple; Pusu. 5-merous; sta. epig.; G 3—5-loc.): Philadelphus, Deutzia, Hydrangea.

IV. PTEROSTEMONOIDEAE (shrubs with alt. stip. simple l.; sta. 10; \$\bar{G}\$ 5-loc.; ov. 4-6, on axile plac.): Pterostemon.

V. ESCALLONIOIDEAE (shrubs or trees, rarely herbs; with simple alt. exstip. often leathery and gland-dotted l.; sta. = pets.; G superior to inferior; ov. ∞): Brexia, Escallonia.

VI. RIBESIOIDEAE (shrubs with alt. simple exstip. 1. and racemes of fls.; \$\bar{G}\$ 1-loc. with 2 parietal plac.; berry): Ribes.

VII. BAUEROIDEAE (shrubs with opp. 3-foliate exstip. 1. and simple axillary fis.; ovary semi-inf. with 2 parietal plac.; loculic. caps.): Bauera.

Saxifrage, Saxifraga; burnet -, Pimpinella; golden -, Chrysosplenium.

Scabiosa (Tourn.) L. (BH. incl. Knautia L., Pterocephalus Vaill., Succisa Neck.). Dipsacaceae. 60 Eur., Medit.; 3 in Brit., incl. S. (K.) arvensis L. (scabious) and S. Succisa L. (devil's-bit scabious). The former has a large head of fls. (class B'); the C is drawn out upon the outer side (cf. Compositae), and this the more the further from the centre of the head. Honey is secreted by the upper surface of the ovary, and protected from rain by hairs. The sta. are ripe first, while the style with immature stigmas is quite enclosed in the C; later the sta. wither and the style occupies their place. The stigmas of the various fis. on the head ripen nearly together.

Scabious, Scabiosa; sheep's bit-, Jasione montana L.

Scabrous (dim. scabrid, scaberulous), scurfy.

Scaevola L. Goodeniaceae. oo Austr., Polynes., trop. coasts. S. Koenigii Vahl furnishes a kind of rice paper; its pith is squeezed flat. It is a char, pl. of trop, beach jungle.

Scald, Cuscuta.

Scale leaves, the scaly l. on the outside of buds, rhizomes, &c., Araceae, Casuarina.

usu. absent in the fam., is repres. by a std. Fl. markedly protog., largely visited by wasps.

Scrophulariaceae (EP., BH. unite II. 7 to Globulariaceae to form fam. Salagineae). Dicots. (Sympet. Tubiflorae; Personales BH.). 200 gen., 2600 sp., cosmop. Most are herbs and undershrubs, a few shrubs or trees (e.g. Paulownia), with alt., opp., or whorled exstip. I. Many exhibit interesting features in the veg. organs. Several are climbers (e.g. Maurandia, Rhodochiton, &c.). The Veronicas of

N.Z. are xero. with resemblance in habit to certain Coniferae. A

number of sp. in III. 2 and 3 (below), e.g. Euphrasia, Bartsia, Pedicularis, grow in swampy grass-land and are parasitic by their roots upon the roots of the grasses. Suckers are formed at the points of contact, in spring; they absorb food till the summer, and later absorb organic compounds from the dead parts of the host, and function for storage of reserve-materials. The plants possess green 1. of their own, and so are able to assimilate.

Infl. racemose or cymose, in the former case usu. a spike or raceme, axillary or term. (every variety in sp. of Veronica). Sol.

Floral diagrams of A, Verbascum nigrum, B, Linaria vulgaris, C, Veronica Chamaedrys; after Eichler.

axillary fls. in many, e.g. Linaria. Cymose infls. usu. dichasia, often united into complex corymbs, &c. Bracts and bracteoles usu. present. In Castilleia the upper 1. and bracts brightly coloured.

Fl. §, +, sometimes nearly reg. (Verbascum, &c.); considerable variety in structure, as illustrated by the floral diagrams given. The bulk of the fam. show the Linaria type. K (5), of various aestivations; C(5), median +, often 2-lipped; A 4 (sometimes 2), didynamous, epipet., the post. sta. sometimes repres. by a std. (e.g. in Scrophularia and Pentstemon). Verbascum and its allies have an actinom. C and 5 sta.; Veronica (g.v.) shows 4 sepals (the post. one of the typical 5 absent), 4 petals (the post. pair of the 5 united), and 2 sta., the C rotate. Other variations occur in the Selagineae, &c. Below the ovary is a honey-secreting disc. G(2), medianly placed (not obliquely as in Solanaceae), 2-loc., with axile plac.; ov. usu. \infty, less commonly few (e.g. Veronica, &c.), anatr.; style simple or bilobed. Fr. surrounded below by the persistent K, usu. a capsule (dehisc. in various ways) or a berry. Seeds usu. numerous, small, with endosp. Embryo straight or slightly curved.

Most have fis. \pm adapted to insect-visits. Müller divides them into 4 types: (1) the Verbascum or Veronica type (see gen.) with open fl. and short tube (bees and flies), (2) the Scrophularia type (wasps), (3) the Digitalis and Linaria type with long wide tubes and the essential organs so placed as to touch the back of the insect (bees), and (4) the Euphrasia type or 'loose-pollen' fl., where the pollen is loose and powdery, and the anthers (protected by upper lip) have spines, &c., so that they may be shaken upon the entrance of the insect, which thus receives a shower of pollen. The fls. are seldom markedly dichogamous, but the stigma usu. projects beyond the sta.

so as to be first touched. Most are capable of self-fert, in default of visits. For further details see gen.

In Linaria, &c. (q.v.) there sometimes appears a terminal fl. to the raceme, and this exhibits *peloria*, having a symmetrical C with spurs to all the petals (cf. Ruta, or compare Aquilegia with Delphinium).

A number are or have been officinal, e.g. Digitalis; most are poisonous. Many favourite cult. orn. plants, e.g. Calceolaria, Mimulus, Pentstemon, Antirrhinum, Linaria, Veronica, Collinsia, &c. Classification and chief genera (after von Wettstein):

A. Two post. C-teeth (or upper lip) cover lat. teeth in bud.

- I. PSEUDOSOLANEAE (all l. usu. alt.; 5 sta. often present):
 - 1. Verbasceae (C with very short tube or none, rotate or shortly campanulate): Verbascum, Celsia.

2. Aptosimeae (C with long tube): Aptosimum.

II. ANTIRRHINOIDEAE (lower 1. at least opp.; the 5th stawanting or staminodial):

a. C 2-lipped; lower lip concave, bladder-like.

. Calceolarieae: Calceolaria.

β. C almost actinom., or 2-lipped with flat or convex lips.

- 2. Hemimerideae (dehisc. caps.; C spurred or saccate at base, with no tube): Alonsoa.
- 3. Antirrhineae (as 2, but with tube): Linaria, Antirrhinum, Maurandia, Rhodochiton.
- Cheloneae (dehisc. caps. or many-seeded berry; C not spurred or saccate; infl. cymose, cpd.): Russelia, Wightia, Collinsia, Scrophularia, Chelone, Pentstemon, Paulownia.
- 5. Manuleae (dehisc. caps.; C as in 4; infl. not cymose, ususimple; anthers finally 1-loc.): Zaluzianskia, Lyperia.
- 6. Gratioleae (as 5, but anthers finally 2-loc.): Mimulus, Gratiola, Torenia.
- 7. Selagineae (drupe or indeh. few-seeded caps.): Hebenstretia, Selago.
- B. Two post. teeth (or upper lip) of C covered in bud by one or both of the lat. teeth.

III. RHINANTHOIDEAE.

a. C-teeth all flat and divergent, or the 2 upper erect.

- 1. Digitaleae (anther-loc. finally united at tip; 2 upper C-lobes often erect; not paras.): Veronica, Digitalis.
- Gerardieae (anther-loc. always separate, one often reduced;
 C-lobes all flat, divergent; often paras.): Gerardia.
- b. 2 upper C-teeth form a helmet-like upper lip. Often paras.
 - 3. Rhinantheae: Castilleja, Melampyrum, Tozzia, Euphrasia. Bartsia, Pedicularis, Rhinanthus.

pepper). Fleshy-leaved xero. Cult. orn. fl. and fol.

seed, the product of the ovule after fert.; it contains the embryo, and if nothing else, is exalbuminous, but may contain reserve material outside the embryo (albuminous), which may be derived from the interior of the embryo-sac (endosperm), or from tissue outside this (perisperm). Usually mentioned after the fr. in descriptions. In form, &c. it may be large or small; spherical, ellipsoidal, &c.; anatr., amphitr., &c. like the original ovule. The testa may be smooth, or covered with small or large tubercles, papillae, granules, ribs, &c.; green, brown, or of other colours; thin or thick, woody (as in Bertholletia), with a fleshy outer layer (as in Bixa, Cycas, Magnolia, Moraea, &c.), hooked or winged (see below), or provided with hairs. It is usu. firm and tough, allowing very little evap. of water from the seed. Its outer cells sometimes have mucilaginous walls and swell when wetted, as in Brassica, Collomia, Linum, Plantago, &c.; sometimes there are scales or hairs upon it and these swell, as in many Acanthaceae. The testa is near, marked with a scar, the hilum, where the stalk separated from the seed.

Many are covered by an extra coat (aril) that is developed like the original integuments, i.e. by a cup-like growth of tissue around the seed from the top of the stalk or rarely from the micropyle. Its 602 SEED

development may be studied in fr. of Euonymus. Arillate seeds in Celastraceae, Commelinaceae, &c., Dilleniaceae, Myristica, Nymphaeaceae, Passiflora, Sapindaceae, Taxus, &c. In Euphorbiaceae the aril remains small and hard and is called a caruncle, but usu. it is fleshy.

The endosp. may be starchy, farinaceous, floury, or mealy (the cells containing starch and when powdered forming a floury dust) as in Triticum, oily as in Papaver, Ricinus, &c., fleshy as in Berberis, horny as in Coffea, hony as in Phoenix and Phytelephas, ruminate (marked by wavy transverse lines which give it a marbled look) as in Anonaceae, mucilaginous, &c.

The embryo (rarely embryos) may be straight, curved, twisted, &c. (and cf. Cruciferae). It may have one, two, or several cotyledons (im-

portant in classification), or rarely none, as in Cuscuta, &c.

Mention must be made of adventitious embryos of Alchornea, Funkia, Nothoscordum, &c., and of the peculiar cases of Ginkgo, and Gnetum, where the seed 'ripens' before fertilisation.

Segments, the free portions of a concrescent K or C.

Segregate, kept separate.

Seguieria Loefi. Phytolaccaceae. 25 S. Am. L. leathery; stipules thorny. Powerful odour of garlic. Cpl. 1. Fr. a samara.

Seidelia Baill. Euphorbiaceae (A. II. 2). 2 S. Afr.

Seidlitzia Bunge et Boiss. Chenopodiaceae (B). I Armenia, Persia. Selagineae (BH.). See Scrophulariaceae and Globulariaceae.

Selaginella Spring. The only genus of Selaginellaceae. 700 chiefly trop.; a few temp. e.g. selaginoides Link on boggy hill sides in Brit. Most live in damp places, esp. in forests, but a few xero. The embryo has a suspensor, and grows directly into the leafy plant which shows a habit very similar to Lycopodium-much-branched stem, often creeping, bearing roots on lower side and l. on upper, with term. cones of sporangia. L. spirally arranged as in most Lycopodiums (e.g. in S. selaginoides), or more commonly in 4 ranks, two outer ones of large, two inner ones of small l., thus giving the stem a dorsiventral structure. The roots in some, e.g. S. Kraussiana A. Br. and S. Martensii Spring, are borne on rhizophores, anomalous stem branches developed at the nodes and exhibiting a sort of intermediate structure between stem and root. The sporangia are placed at the bases of the l. in term. cones of radial symmetry. The mega-sporangia contain ▲ large spores and can easily be distinguished by eye. On germ. a microspore produces a rudimentary of prothallus bearing an antheridium. The megaspore forms a 9 prothallus, which remains enclosed in the burst spore, and has an upper small-celled green portion and a lower large-celled storage portion as in Salviniaceae, &c.

S. lepidophylla Spring is a zero. which curls into a ball in the dry season, and may be rolled about by wind (cf. Anastatica).

Selaginellaceae. Lycopodiales. Only genus Selaginella (q.v.).
Selago L. Scrophulariaceae (11. 7). 140 S. and trop. Air., Madag.

Sola, Aeschynomene aspera L.

Solanaceae (EP., BH. incl. Nolanaceae). Dicots. (Sympet. Tubiflorae; Polemoniales BH.). 72 gen., 1500 sp. trop. and temp.; chief centre C. and S. Am., where there are 36 local gen.; in Eur. and As. only § 2 is repres. Herbs, shrubs or small trees; l. in the non-flowering part usu. alt., but in the infl.-portion alt. or in pairs; the arrangement in pairs is due to the mode of branching and adnation as illustrated in the figure. In Datura the branching is dichasial, and the bracts are adnate to their axillary shoots up to the point at which the next

Branching in Solanaceae (after Eichler): Datura Stramonium (left) and Atropa Belladonna (right). 1, 2, 3, firs. or infls. of successive orders; b, bract of 1, a β bracts of 2, and so on.

branches arise, so that a looks like the bracteole of 2, rather than its bract. In Atropa the branching is cincinnal, one of the two branches at a node remaining undeveloped, and the bract is again adnate to its axillary branch. Of the pair of 1. thus found at any node, one is usu. smaller than the other. In Solanum, &c. further complications occur (see Eichler's Bluthendiag.).

Fls. sol. or in cymes, v, sometimes 4. K (5), persistent; C (5), of various forms, rarely 2-lipped, usually folded and conv.; A 5, alt.

with petals, epipet., or fewer in fils., often opening by pores; \underline{G} (2), obliquely placed in the fl. (the post. cpl. to the right, the ant. to the left, when shown in a floral diagram), 2-loc., sometimes with secondary divisions (e.g. Datura), upon a hypog. disc; ov. $1-\infty$ in each loc., anatr. or slightly amphitr., on axile plac. (most often the plac. are swollen and the ov. numerous); style simple, with 2-lobed stigma. Berry or caps. Embryo curved or straight, in endosp. Fls. conspic., insect-visited; some, e.g. Nicotiana, suited to Lepidoptera. A few are economically important, e.g. Solanum (potato), Nicotiana (tobacco), Lycopersicum, Capsicum, &c.; Datura, Atropa, &c. are medicinal; several are favourites in horticulture.

Classification and chief genera (after von Wettstein): the S. are nearly related to Scrophulariaceae, the most general distinction being the oblique ovary: this however is by no means easily made out, and the zygomorphism of the fl. is most often used as a distinction. Certain genera of S. are nearly related to various Boraginaceae, Gesneriaceae, Nolanaceae, &c., and it is possible that the S. are not really a simple monophyletic family; they occupy a middle place between

the Tubuliflorae with actinom. and those with zygom. fls.

A. Embryo clearly curved, through more than a semicircle. All 5 sta. fertile, equal or only slightly different in length.

 Nicandreae (ovary 3—5-loc., the walls of the loc. dividing the placentae irregularly): Nicandra (only genus).

Solaneae (ovary 2-loc.): Lycium, Atropa, Hyoscyamus, Physalis, Capsicum, Solanum, Lycopersicum, Mandragora.

3. Datureae (ovary 4-loc., the walls dividing the placentae equally): Datura, Solandra (only genera).

Embryo straight or slightly curved (less than a semicircle).
 Cestreae (all 5 sta. fertile); Cestrum, Nicotiana, Petunia.

5. Salpiglossideae (2 or 4 sta. fertile, of different lengths): Salpiglossis, Schizanthus.

Solandra L. = Hydrocotyle Tourn. (BH.) = Centella L. p.p. (Umb.).

Solandra Sw. Solanaceae (3). 6 trop. Am.

Solanopsis Börner (Solanum p.p.). Solanaceae (2). 2 Am.

Solanum (Tourn.) L. (incl. Lycopersicum Hill). Solanaceae (2), 1225 trop. and temp. S. Dulcamara L. (bittersweet, nightshade) and S. nigrum L. in Brit. The fls. are small, with a cone of anthers opening at the tip as in Borago. S. tuberosum L. (S. Am.) is the potato. From the axils of the lowest l. there spring branches which grow horiz, underground and swell up at the ends into tubers (potatoes). That these are stem structures is shown by their origin and by their possession of buds—the 'eyes.' Each eye is a small bud in the axil of an aborted l. (repres. by a semicircular rim). When the parent plant dies down in autumn the tubers become detached, and in the next season they form new plants by the development of the eyes, at the expense of the starch and other reserves stored in the tuber. By heaping earth against the stem, so as to cover more of the leaf-axils, more of the axillary shoots are made to become tuber-bearing; hence the value of ridging potatoes. S. Lycopersicum L. (Am.) is the tomato, cult. for ed. fr. S. Melongena L., the egg-fruit, is cult. in warm countries for ed. fr.

Stalagmitis Murr. = Garcinia L. p.p. (Guttif.).

Stamen, a microsporophyll in a fl., usu. a stalked organ, or filament, bearing an anther, the latter composed of 2 lobes or thecae, united by a prolongation of the filament, the connective, each lobe with two pollen sacs, opening by a definite line of dehiscence, or pore, to allow

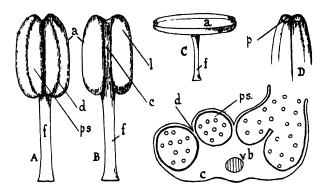

escape of pollen.

The androeceum or stamens may be hypo-, peri- or epi-gynous; epi-phyllous-, -petalous, or -sepalous (concrescent with P, C, or K); diplostemonous (in two whorls, the outer alt. with the C, and as numerous), obdiplostemonous (in two whorls, the outer opp. or anteposed to the pets., Caryophyllaceae), haplo- or iso-stemonous (in one whorl, alt. or anteposed to C, as in Primulaceae), or in 2 whorls (Rosaceae). The sta. may be few and definite (usu. under 20, often described as mon-, di-androus, &c., according to the number), or indefinite (over 20, Ranunculaceae, Rosaceae, &c.); they may be all free (monandrous... polyandrous), or concrescent in 1, 2, 3, many bundles (mon-, di-, tripoly-adelphous) with free anthers, or including the anthers into one mass (synandrium, adj. synandrous) as in many Araceae, Cucurbitaceae. Cyclanthera, Phyllanthus sp.; they may be concrescent also with the gynaecium (gynandrous, Orchidaceae), or have the anthers only united (syngenesious, Compositae). There may be two sta. longer than the rest (didynamous, Labiatae), or 4 (tetradynamous, Cruciserae).

The anther may be sessile or on a filament; may be joined to the filament by its whole length (adnate, dorsifixed, A in fig.) or by its base (innate, basifixed), or balanced on it, forming a T (versatile, C);

Moore.

may be extrerse or introrse (opening away from or towards, centre of fl.). Its dehiscence may also be longitudinal (A), or transverse, valvular (by lids, Berberidaceae, Lauraceae), or by pores (Ericaceae, Gentianaceae), &c., D. The thecae may be twisted as in Cochliostema, Columelliaceae, Cucurbitaceae. The pollen sacs may be numerous. as in Viscum, &c., septate or chambered (Mimoseae, some Onagraceae.

A, stamen with adnate anther from the front; B, the same from the back. C, stamen with versatile anther D, tip of an anther with porous dehiscence. E, cross section of a ripe adnate anther to show pollen-sacs; the two sacs in the right-hand lobe have just opened. a, anther, c, connective, d, line of dehiscence, f, filament, l, anther-lobe, p, pore, p.s. pollen-sac, v.b vascular bundle.

There may be appendages on the filaments (Amaryllidaceae, Hydrophyllaceae, Zygophyllum), or on the anthers (Ericaceae, Melastomaceae). The pollen may be smooth, or warty, powdery or coherent, waxy, &c.; it may be united into groups of 4 grains (tetrads, Ericaceae, &c.), or masses (pollinia, Asclepiadaceae, Orchidaceae). Staminate fl., male.

Staminode, an aborted or vestigial stamen, Acapthaceae, Araceae, Canna, Orchidaceae, Pentstemon, Scrophularia; be small and papilla-like or petaloid (Canna, Marantaceae), nectary, (Loasaceae).

  Stipa L. Gramineae (8). 250 trop. and temp., usu. xero. S. pennata
    L. (feather grass, Steppes) and others have I. which roll inwards when
    the air is dry, covering the stomata and green tissue (which are on the
```

upper side only) and exposing only the woody lower surface. The awn of the fr. is long, ending in a long feather, and hygroscopic, curling up when dry and uncurling when damp. The fr. is thin and sharply pointed, with backward-pointing hairs on the tip. As in Erodium, the awn when damped uncurls, and, if the point of the fr. be on the soil and the feather be entangled with other objects, drives the fr. into the soil. When the air dries the feather is drawn down, not the fr. up. S. tenacissima L. (N. Afr.) is the esparto grass, from which paper is extensively made.

Stipe, a stalk or leafstalk; -itate, on a special stalk.

Stipecoma Muell.-Arg. Apocynaceae (II. I). I C. Brazil.

```

Strychnos L. Loganiaceae. 200 trop. Some, e.g. S. Nux-vomica L. (India, Ceylon), are erect trees, others are climbing shrubs, with curious hook-tendrils. The hook is a modified axillary shoot; the l. in whose axil it arises usu. becomes a scale 1. If the hook catch upon a support it twines close round it and thickens and lignifies (cf. Clematis). Other sp. have axillary thorns. A few have a 1-loc, ovary with free-central placenta. Fr. a berry; the flesh is harmless, but the seeds are exceedingly poisonous, owing to the presence of strychnine in the seed-coats. From these seeds the alkaloid is chiefly obtained. S. toxifera Schomb. (S. Am.) yields the famous wourali or curare poison, with which the S. Am. Indians poison their arrows; it is obtained from the bark by scraping and maceration in water. The seeds of S. potatorum L. f. (clearing nut) are used to purify dirty water for drinking. rubbed on the inside of the vessel, and cause precipitation.

Coniferae (Pinaceae 28; see C. for gen. char.). 2 N. Am. (swamp-cypresses), T. distichum Rich. and T. mexicanum Carr. In the former, esp. in swampy ground, curious 'knees' are formed, hollow spherical branches projecting upwards from the roots, and supposed to be aerating organs

(cf. Sonneratia).

Taxonomy, classification of plants by their affinities. Taxotrophis Blume. Moraceae (1). 6 Indonal.

Taxus (Tourn.) L. Coniferae (Taxaceae, 9; see C. for gen. char.). 8 N. temp., incl. T. baccata L., the yew. No short shoots, but the l. of the spreading branches arrange themselves ± closely in two rows with their upper surfaces nearly in one plane, giving a dorsi-ventral structure to the shoot. Fls. dioec., sol. in the axils of the l. of the preceding year. The 3 has a few scale-l. below and about 8 or 10 sta., each of which is shield-shaped with a number of pollen-sacs on the axial side of the shield arranged round its stalk like the sporangia in Equisetum. The 2 has a rather complex structure. The primary axis bears scale-l. only. In the axil of one of the uppermost of these arises a shoot, continuing the line of the first axis and bearing 3 pairs of scales and a term. ovule. This is orthotr. with one integument, and develops into a seed surrounded by a cup-shaped red and fleshy aril.

The wood of the yew is valuable; in the middle ages it was the chief material used in making bows. The l. are very poisonous, but the aril is harmless. Birds swallow it, and thus dist. the seeds.

Tectona L. f. Verbenaceae (4). 3 Indomal. T. grandis L. f. is the teak, cult. in Java, India, &c., for its timber, which is very hard and durable; enormous quantities are used for ship-building, &c. There are two areas of teak, in the W. peninsula and Burma; it grows in deciduous forest, but not gregariously. The wood sinks in water unless thoroughly dried; this is effected in India by the process of 'girdling,' which consists in removing a ring of bark and sap-wood from the tree near the base. It soon dies, and is left standing for two years.

Tiles, cf. Bamboos.

Tilia (Tourn.) L. Tiliaceae. 18 N. temp. T. platyphyllos Scop. and other limes in Brit. Note leaf-mosaic (see fam.). The l. are usu. covered with honey-dew (see Acer). Fls. in little cymes, arising from axils of l. of current year; the axillary growing point elongates transversely, giving rise to two buds, one of which forms the infl., the other the bud for the next year's growth. The further development of the infl. is complex, but throughout there occurs 'adnation' of bracts to the axes arising in their axils, particularly noticeable in the first l. of the infl.-axis, which forms a wing, covering the fls. Honey is secreted at the base of the sepals. Fls. protandrous, dependent upon insects for fert.; largely visited by bees &c., and a valuable source of honey. Fr. a nut. Endosp. very oily. The wood of lime and of T. americana L. (bass-wood) is useful. The inner fibre of the bark (bass) is very useful for tying.

Tiliaceae (EP.; BH. incl. Elacocarpaceae). Dicots. (Archichl. Malvales). 35 gen., 380 sp., trop. and temp., chiefly S.E. As. and Brazil. Trees or shrubs, rarely herbs, with alt. stip. 1., often showing well-marked

2-ranked arrangement. In the trees the shoots spread out horiz, and the insertions of the l. are upon the upper half, so that the divergence is not 1. The end bud of the branch does not develop in the next year. Frequently the l. is asymmetrical, with the smaller side towards the branch. In the herbs the l. are in two ranks diverging at a right angle; torsion of the l. occurs later on and produces a dorsiventrality. The infl. is always, at least after the first branching, cymose, and often very complex, e.g. in Tilia and Triumfetta (q.v.).

Fl. usu. &, reg., 5-4-merous. K 5 or (5), valvate: C 5, rarely o, often glandular at base; A usu. ∞ , free or united in groups, inserted at base of petals or on androphore, with dithecous anthers; $G_2 - \infty$ -loc., with 1-∞ ov. in each; ov. usu. ascending, ± anatr.; style simple, with capitate or lobed stigma. The T. yield useful timber, jute (Corchorus) and other fibre. The most constant distinction from Malvaceae is in the dithecous anthers, from Theaceae in the valvate calyx, &c. Chief genera: Corchorus, Sparmannia, Tilia, Grewia, Triumfetta.

Tiliacora Colebr. Menispermaceae. 15 Indomal.

Tillaea Mich. ex L. Crassulaceae. 20 cosmop. (1 Brit.).
Tillaeastrum Britton (*Tillaea* p.p.). Crassulaceae. 2 N. Am.

Tillandsia L. Bromeliaceae (1). 400 warm Am. Some resemble the rest of the fam.—epiphytes with pitchers—while others, and especially T. usneoides L. (long moss, Spanish moss, old man's beard, vegetable horsehair), show a different habit, hanging in long grey festoons from the branches of trees, looking rather like a lichen (esp. Usnea). At the base, each of the pendent stems is wound round its support, and as the apex grows on downwards the older parts die away, leaving the axile strand of sclerenchyma (the 'horsehair'). The whole pl. is thickly covered with the usual scaly hairs for absorbing the water trickling over it. It has no storage reservoir for water at The fls. appear but rarely. The pl. is largely distributed from tree to tree by the wind. Birds also use it for nesting and thus carry it about. [See Schimper, Die epiph. Vegetat. Amerikas, p. 67, Plate II.] It is used like horsehair. Some cult. orn. infl.

Filler, a sucker from base of stem.

Filmia O. F. Cook (Martinesia p.p.). Palmae (IV. 2). 2 trop. S. Am. Timber, any woody growth of sufficient thickness to be workable into useful objects. The wood of a stem (Dicot.) grows in thickness, adding one layer each year (in temp. zones), recognizable in cross section as a ring of growth, or annual ring. In the trop., the rings are not usu. so clear, and more than one may form in a year. longitudinal section (esp. radial), the medullary rays of the wood show as the silver grain. As a rule the sap runs up in the outer part of the wood (sap-wood or alburnum), while the inner part becomes more dry and hard (heart-wood or duramen). The pores in the wood seen in cross section are the large vessels in which the sap runs, and the greater the proportion of them (e.g. in climbing plants) the more coarse-grained is the wood.

Physical characters, such as hardness, weight per unit bulk, density or compactness of grain, breaking strain, fuel value, and the like, are

also of great importance.

By far the most important source of timber is the Coniferae (q.v.),

which give the deals, firs, pines, larches, hemlocks, spruces, cypresses, &c. Among the oo other important genera are Acacia (blackwood), Aca (maple), Adenanthera, Afzelia, Arlanthus, Albizzia (siris), Andira, Arctostaphylos (manzanita), Artocarpus (jak), Baphia (camwood), Barringtonia, Bassia, Berrya (Trincomali wood), Betula (birch), Bombax, Brosimum, Brya (cocus, Jamaica ebony), Bucklandia, Buxus (box), Cabralea, Caesalpinia (Brazil-wood, sappan), Calophyllum, Caraipa, Carva (hickory), Carvocar, Castanea (chestnut), Casuarina (ironwood, beefwood), Catalpa, Cecropia, Cedrela (cedar, toon), Celtis, Cercis, Chickrassia (Indian red wood), Chloroxylon (satinwood), Copaifera, Cornus, Corylus, Crataegus (hawthorn), Cupania, Curtisia (assegai wood), Dalbergia (rosewood, &c.), Dimorphandra (mora). Diospyros (ebony, &c.), Dipterocarpaceae, Duguetia (lancewood), Ebenaceae, Eperua (wallaba), Erica (bruyere, briar), Erythrina (kaffirboom), Eucalyptus (gum, karri, jarrah, &c.), Euonymus (spindlewood), Fagara (W.I. satin), Fagus (beech), Feronia, Ficus, Flindersia, Fraxinus (ash), Garcinia, Gleditschia, Gmelina, Grevillea (silky oak), Guaiacum (lignum vitae), Haematoxylon (logwood), Heritiera, Herminiera, Hymenaea, Ilex (holly), Jacaranda, Juglans (walnut), Khaya (Afr. mahogany), Lagerstroemia, Laurelia, Laurus, Leguminosae, Liquidambar (satin walnut), Liriodendron (white wood), Lophira (Afr. oak), Maba, Machaerium, Maclura (bowwood), Melaleuca, Melanoxylon, Melia, Mesua, Metrosideros (rata), Michelia, Mimusops, Murraya, Myoporum, Nectandra (greenheart), Nyssa, Ochroma (corkwood), Ocotea (stinkwood), Olea (olive, N.Z. maire), Oldfieldia (Afr. oak), Ostrya (leverwood), Palmae (several, such as Borassus, Cocos, &c. give useful small timber), Pappea, Pericopsis, Peumus, Pittosporum, Planera, Platanus (plane), Populus (poplar), Pterocarpus (padouk, red sanders), Quassia, Quercus (oak), Robinia (locust), Royena (zwartbast), Salix (willow), Santalum (sandalwood), Schleichera (Ceylon oak), Shorea (sal), Sophora, Stenocarpus (beefwood). Swartzia (beefwood), Swietenia (mahogany), Tectona (teak), Terminalia, Tilia (lime, basswood), Tristania (brushbox), Ulmus (elm), Vatica, Xylia, Zelkova, Zizyphus (cogwood), and many more. It should be noted that the common name of a timber is no proof of its botanical origin. New timbers brought upon the market must be given familiar names, and Swietenia as a source of mahogany, for example, has been almost superseded by Khaya. For details see Stone's Timbers of Commerce, and Gamble's Indian timbers, and manuals of forestry.

Tridophyllum Neck. (Potentilla p.p.). Rosaceae (III. 2). 9 Am.

Trientalis Rupp. ex L. Primulaceae. 3 N. temp. T. europaea L. (chickweed winter-green) in Brit. Rhiz. with erect stem bearing about 4-7 l. in a tuft and a few 7-merous fls.

Trifax Nor. Inc. sed. Nomen.

Trifolium (Tourn.) L. Leguminosae (111.4). 290 temp. and subtrop.; 20 in Brit. (clover, trefoil, shamrock). The fl. has the simplest mechanism in the fam., the sta. and style emerging as the keel is depressed by an insect resting on the wings, and returning when it is released. The fls. of white clover are an important source of honey; those of red clover are too long-tubed for hive-bees and are visited by humble-bees. T. subterraneum L. has two kinds of infl., one normal, the other becoming subterranean. Only 3 or 4 of its fis. develop, the rest forming grapnels (each sepal forming a reflexed hook); the stalk of the infl. bends downwards and gradually forces the fis. under the earth, where the fr. ripen (cf. Arachis). T. badium Schreb. has a wing upon the fr. formed by the persistent C., T. fragiferum L. a bladdery 'wing' formed by the K. The clovers are important pasture and hay plants; among the chief are T. repens L. (white or Dutch clover), T. pratense L. (red clover), T. hybridum L. (alsike), &c.

Triglochin Riv. ex L. Scheuchzeriaceae. 12 cosmop.: 2 in Brit. (arrowgrass), in fresh water- or salt-marshes (T. palustre L. and T. marstimum L.). Tufted herbs with leafless fig. scapes ending in spikes or racemes. L. linear, fleshy in the maritime sp. P 3+3, A 3+3, G (3+3), or sometimes 3 with 3 abortive cpls. between the fertile. By a process of secondary growth the inner whorl of P comes to stand higher on the axis than the outer sta. Fl. protog., wind-pollinated. The pollen collects in the hollowed bases of the P-leaves. The ripe cpls. surround a central beak (cf. Geranium), and are prolonged outwards at the base into long sharp spines, by whose means, breaking away from the beak, they may be animal-distr.

Trigonachras Radlk. (Sapindus p.p. BH.). Sapindaceae (1). 4 Malaya. Trigonella L. Leguminosae (III. 4). 70 Medit., Eur. (I Brit.), As., S. Afr., Austr. T. Foenum-graecum L. (fenugreek) is sometimes cult. as curry stuff and for veterinary medicine. The fls. of T. Aschersoniana Urban bury themselves like those of Arachis.

Ulearum Engl. Araceae (VII). I Upper Amazon valley. Uleophytum Hieron. Compositae (2). I Peru. Climber.

Ulex L. Leguminosae (III. 3). 20 W. Eur., N. Afr.; 3 in Brit., U. europaeus L., U. nanus Forst. and U. Gallii Planch., the gorse, furze, or whin, covering large areas, esp. on heaths. The l. are reduced in size, and many branches reduced to green spines (xerophytism). The fls. explode like Genista, and the fr. explodes by the twisting up of its valves in dry air. The seeds in germination show interesting transition-stages from the usual compound 1. seen in the order to the needle-1. of the mature pl. (cf. Acacia).

Uliginosus (Lat.), growing in swamps.

Ullucus Caldas. Basellaceae. 1 Andes, U. tuberosus Caldas. Lat. branches of the rhiz. swell into tubers like potatoes, and are used as food.

Ulmaceae (EP.; Urticaceae p.p. BH.). Dicots. (Archichl. Urticales). 13 gen., 130 sp., trop. and temp. Trees with sympodial stems, bearing 2-ranked simple often asymmetrical 1. with stips. Fls. usu. in cymose clusters, generally unisexual. P 4—5, free or united, sepaloid, theoretically belonging to two whorls; A 4—5, opp. the perianth-1., in two whorls; G rudimentary in & fl., in the ? of (2) cpls., sometimes 2-loc. but usu. 1-loc., the second loc. aborting; ov. 1 per loc., anatr. or amphitr., pend., style linear or bifid. Nut, samara or drupe. Seed usu. with no endosp. The wood of many is useful. Chief genera: Ulmus, Celtis.

Ulmaria (Tourn.) Hill (Spiraea p.p. BH.). Rosaceae (III. 4). 10 N. temp. U. palustris Moench (Spiraea Ulmaria, meadow-sweet) and U. Filipendula Hill (S. Filipendula, dropwort) in Brit.

Ulmus (Tourn.) L. Ulmaceae. 18 N. temp. and Mts. of trop. Asia.

U. montana With. (wych elm) and U. campestris L. (elm) in Brit. Growth sympodial, the term. bud being suppressed. L. asymmetrical, one side larger than the other (cf. Begonia). The fis. are y and come out before the l. as little reddish tufts, each a short axis with a number of l., beginning 2-ranked at the base and going over to 5-ranked above. There are no fis. in the axils of the lowest 10 or 12; in the axils of the upper l. are fis. arranged in small dich. cymes (cf. Betulaceae), which are reduced, in U. campestris and others, to the one central fi. Each fl. has P 4—8 and as many sta. with 1-loc. ovary. [See Chalazogamae.] Fr. a samara. The elm supplies a valuable timber.

Umbel, an infl. in which the stalks of the fis. all spring from the top of the main stalk.

Umbeliales (BH.). The 15th order of Polypetalae.

Umbelliferae (EP., BH.). Dicots. (Archichl. Umbelliflorae). 200 gen., 2700 sp., cosmop., chiefly N. temp. Many in Brit. Most can be recognized by habit; herbs with stout stems, hollow internodes, and alt. exstip. sheathing I. with their blades much divided pinnately. A few, e.g. Hydrocotyle and Bupleurum, have entire l. Infl. usu. a cpd. umbel. At the top of the stalk of each partial umbel, an invol. of bracts is often found (the bracts of the outer fls.), and a similar larger invol. often occurs at the top of the main stalk bearing the cpd. umbel; the latter is sometimes termed the involucre in contradistinction to the involucels of the partial umbels. A term. fl. often occurs, e.g. in Daucus. In a number of genera (e.g. Astrantia, Hydrocotyle) simple umbels occur, cymose in type (as the non-centripetal order of opening of fis. shows) and often arranged in cymose groupings, e.g. in Sanicula. Eryngium has a cymose head. Some sp. of Xanthosia and Azorella have such cymose infls. reduced to single fls., and these infls. have commonly invols. of bracts.

Fl. usu. § and reg. (see below), epig. K 5, usu. very small, the odd sepal post.; C 5 (rarely o), usu. white or yellow; A 5, intr.; G (2), antero-post., 2-loc.; in each loc. one pend. ovule, anatr., with ventral raphe. On top of the ovary is an epig. disc, prolonged into two short styles.

The massing of the fls. into dense infls. makes them conspic. (cf. Compositae), and this is aided by the zygomorphism of the C often

seen; the outer petals of the outer fls. are drawn out (cf. Cruciferae) so as to form a sort of ray. Honey is secreted by the disc; it is accessible to all insects (fam. in class A). The chief visitors are flies; fls. very protandrous, the cf. stage being most commonly over before the ? begins.

The ovary ripens into a very char. fruit, a dry schizocarp, which splits down the septum between cpls. into 2 mericarps, each containing one seed. The two are generally held together at first by a thin stalk (carpophore) running up between them. The structure of the pericarp is of great import-

Floral diagram.

ance in determining the gen. It is nearly always necessary to have ripe fr. in order to identify one of the U. The shape is often im-

portant; the outer surface of each mericarp has generally 5 projecting primary ridges, two of which (the lateral ridges) are at the edges where the splitting takes place. Between these are sometimes secondary ridges, 4 to each mericarp. In the furrows are often found oil-cavities (seen as small openings in cross-section) known as vittae. The seed is often united to the pericarp; it is album. with small embryo in oily endosp., which is usu. cartilaginous in texture. The shape of the endosp as seen in cross-section is of importance; it may be crescentic, or ventrally grooved, or concave on ventral side. The fr. often shows adaptations for distr.; in many (e.g. Heracleum and allies) the mericarp is thin and flat, suited to wind-carriage; in others (e.g. Daucus) it has hooks. See also Scandix.

Many U. are economically useful, but as a rule they are poisonous. See Daucus (carrot), Pastinaca (parsnip), Apium (celery), Crithmum (samphire), Foeniculum (fennel), Archangelica, Carum, Ferula, Pimpinella, Coriandrum, Petroselinum, &c.

Classification and chief genera (after Engler):

I. HYDROCOTYLOIDEAE (fr. with no free carpophore, and woody endocarp: vittae none or in main ribs).

 Hydrocotyleae (fr. with narrow surface of union, lat. flattened): Hydrocotyle, Azorella.

2. Mulineae (fr. with flattened or rounded back; **): Bowlesia

- II. SANICULOIDEAE (endocarp soft, exocarp rarely smooth; style long with capitate stigmas, surrounded by ring-like disc; vittae various).
 - Saniculeae (ov. 2-loc.; fr. 2-seeded, with broad surface of union; vittae): Eryngium, Astrantia, Sanicula.

2. Lagoecieae (ov. 1-loc.; fr. 1-seeded; vittae indistinct);

Lagoecia.

III. APIOIDEAE (endocarp soft, sometimes hardened by subepidermal fibre layers; style on apex of disc; vittae).

A. Primary ridges projecting, the lat. sometimes wing-like; no secondary ridges.

a. Secondary umbels each with 1 or few ? fis. surrounded by s.

 Echinophoreae (fr. enclosed by hardened stalks of & fis.): Echinophora.

b. Fls. all &, or irreg. polygamous.

a. Seed at surface of union deeply forked or hollow.

2. Scandicineae (parenchyma around carpophore with crystal layer): Chaerophyllum, Anthriscus, Torilis.

- Coriandreas (without crystal layer; fr. ovate-spherical, nutlike, rarely long, with woody sub-epidermal layer): Coriandrum.
- 4. Smyrnieae (narrow surface of union, mericarps rounded outwards): Smyrnium, Conium.

β. Seeds flattened at surface of union.

 Ammineae (primary ridges all alike; seed semicircular in section): Bupleurum, Apium, Petroselinum, Carum, Pimpinella, Seseli, Foeniculum, Oenanthe, Ligusticum. Peucedaneae (lat. ribs much broader, forming wings; seed narrow in section): Angelica, Ferula, Peucedanum, Pastinaca.

B. Lat. ridges equal or larger than primary; vittae in furrows or under secondary ridges.

 Laserpitieae (secondary ridges very marked, often extended into broad undivided or wavy wings): Laserpitium, Thansia.

8. Dauceae (ribs with spines): Daucus.

Umbelliflorae. The 30th order (EP.) of Archichlamydeae; the 23rd (Warming) of Choripetalae.

Price (Tourn.) L. Urticaceae (i). 30 temp. (nettles). Herbs with opp. 1. and stips. (sometimes united in pairs between the petioles, as in Rubiaceae), usu. covered with stinging hairs. The various types of infl. are well shown in the 3 Brit. sp. 1n general the infl. is a dich. cyme with tendency to cincinnus by preference of the β -bracteole. In U. pilulifera L. (Roman nettle) the δ and δ infls. spring side by side from each node, the δ catkin-like, the δ a pseudo-head. In U. urens

L. (small nettle) a panicle is formed containing both 3 and ? fls. In U. dioica L. (large or common nettle) there is a panicle, but each sex is confined to its own plant. P4; A4, opp. to P leaves. The sta. are bent down inwards in the bud, and when ripe spring violently upwards and bend out of the fl., the anther turning inside out, so that the loose powdery pollen is ejected as a little cloud, and may be borne by wind to the stigma. The ? fl. has a r-loc., r-ovuled ovary with a large brush-like stigma. Achene enclosed in the persistent P. Young tops eaten like spinach. Useful fibre from stems.

Urticaceae (EP.; BH. incl. Moraceae, Ulmaceae, Cynocrambaceae). Dicots. (Archichl. Urticales). 41 gen., 480 sp., trop. and temp. Most are herbs or undershrubs, with no latex, and with alt. or opp. stip. Infl. cymose often 'condensed' into pseudo-heads, &c. Fls. usu. unisexual and reg. P 4—5, free or united, sepaloid; sta. as many, bent down inwards in bud and exploding when ripe; G 1-loc. with 1 erect basal orthotr. ov. and 1 style. Achene. Seed usu. with rich oily endosp.; embryo straight. Boehmeria, Urtica, Maoutia and others are used as sources of fibre.

Classification and chief genera (after Engler):

A. With stinging hairs. P (4-5) in ?. L. alt. or opp.

1. Urereae: Urtica, Urera, Laportea.

B. No stinging hairs.

- 2. Procrideae (P of ? 3-merous, stigma paint-brush-like): Pilea, Pellionia, Elatostema.
- 3. Boehmerieae (& usu. with 4-5 sta. No invol.): Boehmeria, Maoutia.
- 4. Parietarieae (P present; bracts often united in invol.): Parietaria.

5. Forskohleeae (& fl. reduced to 1 sta.).

Ulmaceae are distinguished by infl., aestivation of sta., and ovule, and Moraceae by presence of latex, and also usu. by ovule, embryo, &c.

Urticales. The 12th order of Archichlamydeae. Cf. p. xii.

Utleria Bedd. Asclepiadaceae (I). I S. India.

Utricle, Cyperaceae.

Utricularia L. Lentibulariaceae. 210 trop. and temp., the latter all aquatic. Some Brazilian sp. are confined to the pitchers of the Bromeliaceae. 3 in Brit.; U. vulgaris L., the bladder-wort, common. The morphology is interesting, for the usual distinctions drawn between root, stem and l. cannot be applied here. The common bladderwort is a submerged water pl. with finely-divided l.; it never has roots, even in the embryo. The fls. project above water on short shoots, and there are also short shoots with small l., which arise from the main axis and grow upwards to the surface. Upon the ordinary submerged l. are borne the bladders, curious hollow structures with

trap-door entrances. Small Crustacea and other animals push their way into the bladders and are not able to escape, for the doors only open from outside. The plant takes up the products of the decay of the organisms thus captured; it is very doubtful whether any special ferment is secreted. Other sp. are land pl. with peculiar runners, which develop in the moss or other substratum, on which they grow, and there bear the bladders. Others again, e.g. U. montana Poir., are epiph. with water storage in tuberous branches. The l. of all these forms are simple. Goebel (Pflanzenbiol. Sch.) has investigated the development of U, and finds that all these parts—1., bladders. runners, water-shoots, erect shoots, &c .- are practically equivalent to one another, and that the same rudiment at the growing point may give rise to any one of them, or that they may themselves change from one to another type. Similarly on germ. a lot of spirally-arranged primary l. are produced, and then one or two water-shoots appear lat. on the growing point, bearing no direct relation to the l. in position, but apparently homologous with them. "Like Genlisea, U. possessed originally a leaf-rosette, ending with an infl., and consisting partly of bladders. Then were added the swimming water-shoots or (in land forms) runners, which though externally unlike leaves (since they develop indefinitely and produce leaves and infls.) yet are originally homologous with them." For further details see Goebel, loc. cit. Hibernation in Brit. sp., &c. by winter buds full of reserves, which drop off and sink.

Veratrin, Schoenocaulon, Veratrum.

Veratrum (Tourn.) L. Liliaceae (1). 50 N. temp. Rhiz. with leafy stem and racemes, lower fls. \$, but upper usu. & by abortion (andromonoecism). Sometimes pl. occur with a fls. only. Protandr. Seeds with membranous border. Veratrin is obtained from the rhiz.; that of V. album L. is known as white hellebore root.

Verbascum Tourn. ex L. Scrophulariaceae (I. 1). 210 N. temp. | *; 6 Brit. (mullein). Large perenn. herbs with stout tap-roots, wrinkled like Taraxacum. Infl. primarily racemose, but lat. fis. often replaced by condensed dichasia (cf. Labiatae). For structure and diagram see fam. Fls. visited for pollen by bees and drone-flies. Those of several formerly officinal (flores Verbasci).

Verbena Linn. Verbenaceae (1). 100 trop. and temp. V. officinalis L., the vervain (Brit.), was formerly in great repute as a remedy in eye-diseases, its bright-eyed C, like that of Euphrasia, being supposed, under the old doctrine of signatures, to indicate its virtues in that

direction. Several cult. orn. perf. fl.

Verbena oil, Lippia, Cymbopogon.

Verbenaceae (EP.; BH. incl. Phrymaceae). Dicots. (Sympet. Tubiflorae; Lamiales BH.). About 70 gen., 750 sp., almost all trop. and subtrop. Herbs, shrubs or trees; many lianes, e.g. sp. of Lantana, Clerodendron, Vitex; xero. also, often armed with thorns, frequent. L. usu. opp., rarely whorled or alt., entire or divided, exstip. Infl. racemose or cymose, in the former case most often a spike or head, often with an invol. of coloured bracts. The cymes usu. dich. with a cincinnus tendency (cf. Caryophyllaceae); sometimes they also form heads.

Fl. usu. \(\forall , \dots \), usu. \(\forall -\text{merous.} \) \(K \) \((5) \) \([\text{or} (4-8)] \), \(\text{hypog.}; \) \(C \) \((5) \), usu. with narrow tube, rarely campanulate, often 2-lipped; A 4, didynamous, rarely 5 or 2, or of equal length, alt. with C-lobes, with intr. anthers; G usu. (2), rarely (4) or (5), usu. 4-lobed, originally 2for more) loc., but very early divided into 4 (or more) loc. by the formation of a 'false' septum in each loc. (cf. Labiatae); plac. axile, with 2 ov. per cpl. (i.e. 1 in each loc. after septation); ovules anato ortho-tr., basal, lat. or pend., but always with the micropyle directed downwards. Style term., rarely = sunk between lobes of ovary (contrast Labiatae); stigma usu, lobed. Fr. generally a drupe. more rarely a caps. or schizocarp. Seed usu. exalbum.

Several are useful as sources of timber, e.g. Tectona. See also

Lippia, Priva, Clerodendron, &c., for other economic uses.

Classification and chief genera (after Briquet):

A. Infl. spicate or racemose. Ovule usu. basal, erect, anatr.

 Verbeneas (no endosperm): Verbena, Lantana, Lippia, Priva, Petraea, Citharexylum.

2. Stilbeae (endosperm): Stilbe.

B. Infl. of cymose type. Cymes often united into panicles, corymbs, &c.; if axillary, often reduced to 1 fl.

. Ovule lat. (sometimes very high up) semi-anatr. Ovary fully

or imperfectly 4-10-loc.

 Chloantheae (fr. usu. drupaceous, never caps.; endosperm): Chloanthes.

4. Viticeae (as 3, but no endosperm): Callicarpa, Tectona, Vitex, Clerodendron.

 Caryopterideae (fr. caps.-like, 4-valved; the valves fall taking the stones with them or loosen them from the placental axis): Caryopteris.

b. Ovule apical, pend., orthotr.

 Symphoremeae (ov. 2-loc. to centre; fr. dry, 1-seeded): Symphorema.

7. Avicennieae (ov. imperfectly 4-loc.; fr. caps., 2-valved, 1-seeded; mangroves); Avicennia (only gen.).

Vernation (arrangement of l. in bud), cf. Leaf.

Vernonia Schreb. Compositae (1). 650 Am., Afr., As., very common in grassy places. Style typical of § 1 (cf. classification of C.).

Veronica (Tourn.) L. Scrophulariaceae (III. 1). 250 extra-trop., many alpine; 17 in Brit. (speedwell). The Brit. sp. are herbaceous (often woody below); fls. in term. or lat. racemes. The post. sepal of the 5 typical of this fam. is absent, and the two post. petals are united into one large one, so that the P is 4-merous (see fam. for diagram). The 2 sta. and style project horiz. from the rotate C. A small percentage of fis. exhibit a different number of parts (e.g. 5 petals). The fert. of the fl. in V. Chamaedrys L., the commonest Brit. sp., is performed chiefly by drone-flies. The style projects over the lower petal, while the two sta. project lat. Honey is secreted at the base of the ovary and concealed by the hairs at the mouth of the short tube. Insects alighting on the lower petal touch the style and grasp the bases of the sta., thus causing the anthers to move inwards and dust them with pollen. The peduncles stand close up against the main stem of the raceme whilst the fis. are in bud, diverge as the fis. open, and again close up as they wither. Caps. with a few flattened seeds suited to wind-distr. In V. arvensis L. and other sp. that live in damp places, the capsule merely cracks as it dries and only opens so far as

to allow the seeds to escape when thoroughly wetted; the seeds then

become slimy (cf. Linum).

Many exotic sp. are shrubby, with handsome spikes of fls.; often cult. In N.Z. the genus is char. alpine; 81 sp. occur, of which 77 are endemic. Some are small trees; most are shrubby. Many, e.g. V. cupressoides Hook. f., are xero. with reduced l. appressed to stem, so that the twigs resemble those of Cupressus and other Coniferae.

Vine, Vitis; (in U.S.) any climbing or running stem.

Vinegar, Borassus, Cocos, Vitis, &c.

Viola Tourn. ex Linn. Violaceae. 400 cosmop., chiefly N. temp. Several in Brit. V. odorata L. and V. canina L. are the sweet and dog violets, V. tricolor L. the pansy or heart's-ease, and others are also well known. Many sp. and vars. cult. Herbs with large stips., on which glands sometimes occur. Fls. usu. one in each axil; sometimes (e.g. V. tricolor) a veg. shoot arises above the fl. in the same axil. The intr. anthers form a close ring round the ovary, below the style, which ends in a variously shaped head on whose ant. surface is

the stigma, often a hollow pocket. The lower pet. forms a landingplace and is often prolonged backwards into a spur, in which collects honey, secreted by processes projecting into it from the lower sta. Honey guides show as streaks upon the C leading to nectaries. These fis. are as a rule incapable of self-fert. In V. tricolor the pollen is shed on to the ant. pet., and the lower edge of the stigma is guarded by a flap which the insect, when withdrawing, closes; and thus the fl.'s own pollen does not reach the stigma. The small-flowered subspecies V. arvensis Murr. has not this flap and fertilises itself. In *V***. odorata** the stigma is merely the bent-over end of the style, and is first touched as the insect enters. The size, colour, &c. of the flower of this sp. and of V. canina render them suited to bees.

In many, e.g. V. canina, V. odorata, V. sylvestris, Lam., the fis. are rarely visited, and little seed is set. They usu flower early in the season; later on appears a second form of fl. on the same pl. These are the cleistogamic fls., which never open, but set seed by self-fert. In V. canina this fl. looks like a bud; the seps. remain shut, there are 5 minute pets, 2 ant. sta. with anthers containing a little pollen (only enough for fert.—there is no waste as in open fis.) and 3 other abortive sta.; pistil much as usual. The anthers are closely appressed to the stigma; the pollen-grains germinate within them, and the tubes burrow through the anther-walls into the stigma. V. odorata has similar fls., but with all 5 sta. fertile. The production of these fls. ensures the setting of seed.

Fr. a 3-valved capsule; seeds very hard and slippery. One plac. with its seeds remains attached to each valve; as this dries it bends upwards into a U-shape, squeezing the seeds against one another and

shooting them out (cf. Claytonia, Buxus).

Violaceae (EP., BH. incl. Sauvagesieae of Ochnaceae). Dicots. (Archichl. Parietales). 15 gen., 800 sp., cosmop. Annual or perennial herbs. or shrubs. L. alt., stip., usu. undivided. Fls. 1 or 2 in each axil, in usu. racemose infls., bracteolate, &, usu. . K 5, persistent; C 5, hypog., usu. ..., the ant. petal often spurred to hold the honey, with descending aestivation; A 5, alt. with petals, hypog., forming a ring round the ovary; filament very short, anther intr., connective usu. with membranous prolongation; G(3), 1-loc. with $1-\infty$ anatr. ov. on each of the parietal plac. Style simple. Fr. a 3-valved loculic. caps. Endosp. Chief genera: Alsodeia, Viola.

Viscid, viscosus (Lat.), sticky.

Viscin, Loranthaceae, Viscum.

Viscum Tourn. ex L. Loranthaceae (II). 20 | *. V. album L. in Brit. (mistletoe) is a semiparasitic shrubby evergr., growing on apple. bawthorn, oak, &c., and drawing nourishment from its host by suckers. It is repeatedly branched in a dich. manner, the central stalk usu. ending in an infl. Each branch bears two green leathery l., and repres. a year's growth. The unisexual dioec, fis, are in groups of three. No calyculus. Sta. completely fused to the P-leaf. Pollensacs very numerous. Ovary as usual. The fis. secrete honey and are visited by flies. Pseudo-berry. The layer of viscin prevents the bird that eats the berry from swallowing the seed, which it scrapes off its bill on to a branch, where it adheres and germinates.

Vitis (Tourn.) L. (BH. incl. Ampelopsis Michx., Cissus L., Quinaria Rafin.). Vitaceae. 40 *. The vines are climbing pl., with tendrils which repres. modified infis.; the stem is usu. regarded as a sympodium, each axis in turn ending in a tendril, but there has been much argument upon the subject. The tendril may attach itself by the ordinary coiling method, or may be negatively heliotropic and thus force its way into the crevices of the support: in these crevices the tips of the tendrils form large balls of tissue, the outer parts of which

become mucilaginous and cement the tendril to its support. V. vinifera L. (Orient, N.W. India) is the cult. grape, cult. in most warm countries. About 3000 million gallons of wine are made every year. When dried the fruits form raisins; the sultana raisin is a seedless var. The currants of commerce are the fruit of the Corinthian variety (current is a corruption of Corinth). V. aestivalis Michx. (summergrape) and V. Labrusca L. (fox-grape) are N. Am. sp. which have been largely introduced into Eur., as they resist the attacks of the dreaded insect, Phylloxera, better than the Eur. sp. For Virginian creepers cf. Parthenocissus.

Water plants (hydrophytes), a well-marked form of veg., contrasting with meso- and xero-phytes. All in this book are derived from land pl.; many are very old, widely dispersed. They show rapid

growth, frequent branching, much veg. repr. They have no rigid anatomy, and are marked by absence of cuticle, stomata, &c., and by presence of enormous intercellular spaces. The 1. shows 4 types, (1) the floating 1. of Hydrocharis, Nymphaeaceae, Ranunculus, Traps, &c., a round l. with cuticle and stomata above; (2) the awl-shaped type of submerged l. of Isoetes, Lobelia, Subularia, &c., plants which can often survive upon land; (3) the ribbon type of most Monocots. e.g. Vallisneria, Potamogeton, Ruppia, Zostera; (4) the much divided type with linear segments, Bidens, Ceratophyllum, Myriophyllum, Podostemaceae, Ranunculus, Trapa, &c. Heterophylly is common, cf. Cabomba, Callitriche, Potamogeton, Ranunculus, Sagittaria, Salvinia, Trapa, &c.

Many hibernate by buds formed at the ends of branches, full of reserves, e.g. Hydrocharis, Myriophyllum, Potamogeton sp., Utricularia, by tubers, Potamogeton, sp., Sagittaria, by rhizomes, Potamo-

geton, sp., Nymphaeaceae. Cf. Lemnaceae.

Most are perennials: annuals in Marsilea. Naias. Subularia. Fls. usu. wind- or insect-pollinated, but Ruppia, Zostera, &c. are fert. under water. The seeds usu. sink, and often show interesting features in germination. A few amphibious pl. exist, which can also live on land, e.g. Littorella, Polygonum. In the trop. occur the interesting fams. Hydrostachyaceae, Podostemaceae, and Tristichaceae (q.v.), in swift water

Wellstedia Balf. f. Boraginaceae (v). 1 Socotra.

Welsh poppy, Meconopsis cambrica Vig. Welwitschia Hook. f. (Tumboa Welw.). Gnetaceae. I sp., W. mirabilis Hook. f. (7. Bainesis Welw.), a remarkable plant discovered by Baines in Damaraland in W. trop. Afr., and shortly afterwards by Welwitsch in Mossamedes, and described by Hooker in Trans. Linn. Soc. 1883 (q.v.). Specimens in most museums. The plant has a peculiar habit, and grows for at least a century, and probably much longer. Its native climate is a markedly desert one, with a mere trifle of rainfall, the bulk of the moisture being derived from sea fogs, which cause a heavy deposit of dew. Seeds are produced in large quantities, and being enclosed in the winged P are blown about, and germinate in the occasional wet years. The stem is stout, with a two-lobed form and almost circular in section. It narrows downwards into a stout tap-root. At the edges of the two lobes are two grooves, from each of which springs a l. These l. are the first pair after the cots. and are the only l. the plant ever has; they go on growing at the base throughout its life, wearing away at the tips and often becoming torn down to the base. The stem continues to grow in thickness, and exhibits concentric grooves upon the top surface. In the outer (younger) of these grooves the fis. appear, in cpd. dichasia of small (3) or larger (2) spikes; they are covered by bracts which become bright red after fert. The fis. are dioec., and are produced annually. Pollination by insects. In the 3, there is a P of 2+2 l., the outer whorl transv. to the bract; sta. 6, united below, with 3-loc. anthers; gynaeceum rudimentary, but with the integument of the ovule looking like a style and stigma. In the ?, the perianth-1. are fused into a tube, and are equivalent to the two outer L of the &; there is no trace of sta. Ovule 1, erect, with the integument drawn out beyond it. Seed with endosp, and perisperm, enclosed in the P which becomes winged. [See Gymnospermae, and Pearson in Phil. Trans. 198, 1906.]

Xanthisma DC. Compositae (3). I Texas. Cult. orn. fl.

Eanthium (Tourn.) L. Compositae (5). 4 Medit. They have been so-widely distr. by man (unintentionally) that it is hard to discover their native place. Fls. in unisexual heads, single or in axillary cymes, the s at the ends of the branches. The ? head has 2 fls., enclosed in a prickly gamophyllous invol., only the styles projecting from it through openings in the two horns of the invol. The frs. are enclosed in the hard woody invol., which is covered with hooks and well suited to animal-distr. One sp. has gradually spread in this way from the East of Europe. "In 1828 it was brought into Wallachia by the Cossack horses, whose manes and tails were covered with the burrs. It travelled in Hungarian wool, and in cattle from the same region, to Regensburg, and on to Hamburg, appearing here and there on the way." Strenuous laws for its extirpation have been enforced in South Africa, where at one time it had become so common as seriously to impair the value of the wool.

Zanthocephalum Willd. Compositae (3). 12 warm Am.

Xanthoceras Bunge. Sapindaceae (11). 2 N. China. Ed. seed.

Xanthocercis Baill. Leguminosae (III. 8). 1 Madag.

Ypsilandra Franch. Liliaceae (1). 1 Tibet. Yuca, cassava, Manihot utilissima Pohl, &c.

Yucca Dill. ex L. Liliaceae (VI). 30 S. U.S., C. Am., W.I. Many cult. orn. (Adam's needle). Stem short, growing in thickness, and branching occasionally (cf. Dracaena); at the end is a rosette of fleshy and pointed l. Fls. large, white, in panicle. Remarkable mode of pollination (for details and figures see Riley in 3rd Aun. Rep. Missouri Bot. Gdn. 1802). This is one of the few cases of mutual dependence and adaptation of a single fl. and a single insect— Pronuba, a moth. The fl. emits its perfume esp. at night, and is then visited by the moths. The female has a long ovipositor with which she can penetrate the tissue of the ovary of the fl., and possesses peculiar prehensile, spinous, maxillary tentacles confined to the genus. She begins soon after dark, collecting a load of pollen, and shaping it into a pellet about thrice as large as her head. She then flies to another fl. and deposits a few eggs in the ovary, piercing its wall with her ovipositor. Having done this she climbs to the top and presses the ball of pollen into the stigma. The ovules are thus fertilised, and are so numerous that there are plenty for the larvae to feed upon and also to repr. the plant.

The leaves of Y. filamentosa L. and other sp. furnish an excellent

fibre (cf. Agave).

Zataria Boiss. Labiatae (VI). 1 Persia, Afghanistan.

Zauschneria Presl. Onagraceae (2). 3 Calif., Mexico. Cult. orn. fl. Zea L. Gramineae (1). 1 sp., Zea Mays L., the maize or Indian corn, apparently originally Mexican, now cult. in most trop. and subtrop. regions. A tall annual grass, with term. o infl. and ? infls. in the axils of the foliage-l. & spikelets in pairs, 2-flowered. The ? infl. forms a 'cob' with long filamentous stigmas hanging out at the end (fis. pollinated by wind). The cob is enveloped when young by large spathe-l., and consists of combined spikes; each two rows of fis. visible on its surface correspond to one spike of fls. The cult. forms are 8-, 10-, 12-, or 24-rowed. Cf. Euchlaena, in which the spikes are distinct and form a tuft. Each spike consists of one-flowered spikelets. Fr. the familiar maize-seed, in which the structure of a grass-fruit can easily be made out; the embryo occupies the white portion near the pointed end.

A most important cereal; it is termed corn in the U.S., like wheat in England, oats in Scotland. The grain is made into flour (Indian meal) or cooked without grinding; green corn (unripe cobs) forms a favourite vegetable, the l. are useful as fodder, the dry cobs as firing; the spathes are used in paper-making, and so on. [See Harshberger's monograph (botanical and economic) in Contrib. Bot. Lab. Univ. Pennsylv. I. 1893.]

Zingiber Adans. Zingiber. 80 As. Labellum large; opp. to it are the style and the petaloid fertile sta. The stigma has many rays. Z. officinale Rosc. is the ginger; it is always repr. by veg. methods, and is quite sterile (of. Musa). Largely cult.; the rhiz. are dug up and killed in boiling water. According to whether the rind is or is not scraped off, the product is known as 'scraped' or 'coated' ginger.

Eingtberaceae (EP, ; Scitamineae p. p. BH.). Monocots. (Scitamineae). 45 gen., 800 sp., trop., chiefly Indomal. Perenn. herbs usu. with sympodial fleshy rhiz., often with tuberous roots. Aerial stem, if any, short; sometimes an apparent stem is formed as in Musa by the rolled up leaf-sheaths. L. 2-ranked, with short stalks and sheathing bases. At the top of the sheath is a char. ligule (cf. Gramineae). Fls. in racemes, heads, or cymes. Their morphology much discussed (see Eichler's Bluthendiag. or Nat. Pfl.). Bracteole often sheathing (as in fig.). K (3), the odd one ant., C 3, usu. different in colour and texture from the outer P-leaves. Of the possible 6 members of the A (two whorls), the post, one of the inner whorl is present as a fertile epipet. sta., and the other two of this whorl are united to form the petaloid labellum (not equivalent to that of Orchids), which may be 2- or 3-lobed; the ant. sta. of the outer whorl is always absent; the other two may be absent (as in Renealmia) or

Floral diagram of Renealmina, modified from Eichler, showing bract, sheathing bracteole, calyx, corolla, labellum (LAB), &c.

may be present as large leafy stds. right_and left of the fertile sta. (cf. with Cannaceae and Marantaceae). G(3), 3-loc., with ∞ anatr. or semi-anatr. ov. Fr. usu. a loculic. caps. Seeds with perisperm. The fam. contains several economic plants; see Curcuma, Costus, Alpinia, Zingiber, Amomum, Elettaria.

Classification and chief genera:

ZINGIBEROIDEAE (l. 2-ranked; lat. stds. different or wanting; pl. aromatic): Hedychium, Kaempfera, Curcuma, Globba, Zingiber, Amomum, Renealmia, Alpinia.

II. COSTOIDEAE (l. alt.; lat. stds. usu. wanting; subaerial parts not aromatic): Costus, Tapeinochilus.

Zones of vegetation, the six zones into which the earth can be divided, occupied by similar types of vegetation with the same periods of growth and the same general adaptation to environment. The divisions are climatic-ecological, and the systematic relationships of the plants are neglected (cf. Floral Regions).

I. The northern Glacial Zone (the arctic region, and all beyond the tree limit, whether towards the poles, or at high levels—the alpine zone). Period of growth usu. short, temperature low, soil liable to be hot in the day, cold at night. Vegetation mainly xerophytic;

veg. repr. well marked.

II. The northern Zane of cold winters (from the N. limit of trees to the region where evergr. begin to predominate and the land is parched in summer). Period of growth 4—7 months; summers not usu. parching. Mesophytism predominant; vast areas covered by forests; heaths and other formations of drier areas common.

III. The northern Zone of hot summers (the subtrop. regions). No real winter, but perhaps an interruption of vegetation in Jan. Xerophytism well marked, though some regions are wet. Forest, copse

(e.g. maqui, chaparral), steppe, and prairie all common.

IV. The tropical Zone (wherever in the trop, the rainfall is enough to prevent the formation of desert). No real interruption of vegetation. Forest (mesophytic) very common, also parkland or savannah.

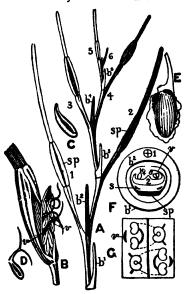

V. The southern Zone of hot summers: much like III.

VI. The southern cold Zone: much like I.

See Schimper, Plant Geography; Warming, Ecological Pl. Geog., &c...

Zornia J. F. Gmel. Leguminosae (III. 7). 12 trop., esp. Am.

Zosima Hoffm. (Zosimia EP.). Umbelliferae (III. 6). 6 W. As. Zostera Linn. Potamogetonaceae. 6 temp., subarct., subtrop., in salt water on gently sloping shores. Z. marina L. and Z. nana Roth. in Brit. (eel-grass or grass-wrack). The lower part of the stem creeps, rooting as it advances, and has monopodial branching; the branches grow upwards and exhibit sympodial branching, complicated by union of axillary shoot to main shoot for some distance

- A. Diagram of branching in floral shoot. 1—6, successive shoots, every other one being shaded; δ¹, δ². fore-leaves on these shoots; sø, spathes (not indicated in the upper shoots). B. Spathe of Z. κανα with flatened spadix taken out; v, the retinaculum; ×2. C and D. Half-anther and pistil of same, more enlarged. E. Fruit of Z. marina, the thin pericarp turned back to show the seed, ×2½. F. Diagram of a main axis, I, with its fore-leaf (δ¹) and the axillary shoot s, with its fore-leaf (δ¹); zø, spathe borne on 2, surrounding the spadix; s, intravaginal scales; v, bracteole. G. Diagram of part of spadix with two flowers: s, bracteole.
- with two flowers; v, bracteole.

 A, F, G, after Eichler; B, C, D, from English Botany; E, after Le Maout and Decaise.

above its point of origin. This is most easily seen in the infl. region; the branching is that of a rhipidium, but shoot 2, which springs from the axil of a l. on shoot 1, is adnate to 1 up to the point at which the first l. is borne on 2; this l. occupies the angle between the two shoots where they separate. Shoot 1 (and 2, 3, &c. successively) is pushed aside and bears an infl. (Eichler's Bläthendiag. or Nat. Pf. for details and figs.) L. long, linear, sheathing at base.

Infl. a flattened spadix, enclosed at flowering time in a spathe (the sheath of the uppermost l.). This is open down one side, and on the corresponding side of the spadix the fls. are borne, the essential organs forming two vertical rows, each composed of a cpl. and a sta.

alt. On the outer side of the spadix next the sta. is often a small l. (retinaculum of systematic works). The midrib of the cpl. faces outwards.

Each cpl. contains one ovule and has two flat

stigmas. The sta. consists of two half anthers, joined by a small connective. It is difficult to decide what is the actual 'flower' in this plant; the usual view is that each sta. with the cpl. on the same

level forms a fl., the retinaculum representing the bract.

Fert. peculiar, Z. being one of the water pl. most completely modified from the ancestral land-pl. type. Fl. submerged like the rest of the pl. The pollen grains are long threads of the same specific gravity as salt water, so that when discharged they float freely at any depth. The stigmas are very large, and thus have a good chance of catching some of the grains. The whole mech. is similar in principle to that of a wind-fert. pl. Fr. an achene. In winter it hibernates without any special modification. The pl. is largely used for packing glass, stuffing cushions, &c., esp. in Venice. [For further details see fam., and Schenk's Wassergewachse.]

Zosterella Small. Pontederiaceae. r Pennsylvania.

Zoysia Willd. Gramineae (3). 3 Masc. Is. to New Zealand.

Zozimia Hoffm. Umbelliferae (III. 6). 6 W. As.

Zachokkea Muell.-Arg. (*Lacmellia BH*.). Apocynaceae (I. I). 8 trop. S. Am.

Zuccagnia Cav. Leguminosae (II. 7). 1 Chili.

Zuccarinia Blume. Rubiaceae (I. 8). I Java.

Zuccarinia Maerklin. Inc. sed. Nomen.

Zuckia Standley. Chenopodiaceae (A). 1 S.W. U.S.

Zuelania A. Rich. (Casearia p.p. BH.). Flacourtiaceae (7). 2 W.I.

Zwackhia Sendtner. Boraginaceae (IV. 5). 1 S.E. Eur.

Zwartbast, Royena lucida L.

zwingera Schreb. = Simaba Aubl. (Simarub.).

Zycona O. Ktze. = Allendea La Llave (Comp.).

Zygadenus Michx. Liliaceae (1). 12 N. Am., Siberia. Zygalchemilla Rydberg (Alchemilla p.p.). Rosaceae (111. 5). 1

trop. Am.

Zyganthera N. E. Br. (Pseudohydrosme p.p.). Araceae (IV). I Gaboon. Zygella Sp. Moore. Iridaceae (II). I Matto Grosso.

Zygia Walp. = Albizzia Durazz. p.p. (Legum.).

Zygo- (Gr. pref.), yoke-; -morphism, symmetry about one plane through axis only, cf. floral diagrams of Labiatas, Papaveraceas, Scrophulariaceae; usu. antero-post., it is diagonal in Solanaceae, transverse in Anigozanthos, Haemodoraceae, some Papaveraceae, right and left-handed in Cassia, Rxacum, Saintpaulia; -te, the cell produced by the union of the sexual gametes.

Zygobatemannia × Rolfe, Zygooolaz × Rolfe, Zygonisia × Rolfe, Zygomena × Hort. Orchidaceae. Hybrids of Zygopetalum with Bate-

mannia, Colax, Aganisia, and Zygosepalum (Menadenium).

Zygodia Benth. Apocynaceae (II. I). 4 trop. Afr. Zygogynum Baill. Magnoliaceae. 3 New Caled.

Zygomenes Salisb. = Cyanotis D. Don (Commel.).

Zygonerion Baill. (Strophanthus p.p.). Apocyn. (11. 1). 1 Angola.

Zygoon Hiern. Rubiaceae (1. 8). 1 Zambesi.

Zygopetalum Hook. (incl. Pescatorea Rchb. f.). Orchidaceae (II. 14). 20 trop. Am. The base of the column forms a chin. Cult. orn. fl.

Tygophyllaceae (EP., BH.). Dicots. (Archichl. Geraniales). 22 gen., 160 sp., xero- or halo-phytes, trop. and subtrop. Most are woody perennials; l. opp., stip., usu. hairy, fleshy or leathery. Fls. in cymes, reg., X. K. 5; C. 5; A. 5 + 5, obdiplost. and with ligular appendages; G. (5), 5-loc. with 1 or more pend. ov. in each loc. Fr. usu. a caps. Seeds with or without endosp. Guaiacum, Peganum, &c. furnish useful products. Chief genera: Zygophyllum, Guaiacum, Porlieria, Larrea, Peganum, Tribulus. Closely related to Rutaceae.

Zygophyllidium Small (*Euphorbia* p.p.). Euph. (A. II. 8). I. N. Am. **Zygophyllum** L. Zygophyllaceae. 60 **, deserts and steppes. L. and

twigs fleshy.

Zygoruellia Baill. Acanthaceae (IV. A). 1 Madag.

Zygosepalum Reichb. f. (Zygopelalum BH.). Orchid. (II. 14). 2 trop. S. Am.

Zygostates Lindl. Orchidaceae (II. 19). 4 Brazil. **Zygostelma** Benth. Asclepiadaceae (II. 1 Siam. **Zygostelma** Fourn. Asclepiadaceae (II. 1). I Brazil.

Zygostigma Griseb. Gentianaceae (1). 2 Brazil, Argentina.

Suggestions for additions to and corrections of the preceding pages can be noted on this slip, which can be detached when desired, signed, and sent to Dr J. C. Willis, c/o University Press, Cambridge

SUPPLEMENT.

TEXT CORRECTIONS, AND NEW GENERA.

The following names given by Rafinesque have been published by Pennell in Bull. Torr. Bot. Club, 48, 1921, p. 92: Actartife, Adenola, Aldinia, Alifiola, Allosandra, Aniketon, Anistelma, Antimion, Antrizon, Artorhiza, Atevala, Atirbesia, Banalia, Bazina, Braxilia, Bucranion, Cargila, Codomale, Dasphora, Dematra, Dilax, Diplandra, Dipleina, Ebraxis, Eudemis, Evactoma, Exemix, Fenixanthes, Festania, Fuisa, Genlisa, Icmane, Idanthisia, Iondra, Iposues, Ixoca, Junia, Kobiosis, Knoxikas, Kumaria, Lepiphaia, Levana, Lomake, Luronium, Marzaria, Merleta, Misopates, Monastes, Monosemeion, Nemelaia, Nevrolis, Odostima, Orthilia, Ozandra, Parmentiera, Pelotris, Perxo, Pleconax, Pleopadium, Plethyrsis, Probatea, Reggeria, Rhizakenia, Rittera, Rodatia, Ronconia, Saliunca, Scubulon, Semetum, Shortia, Smidetia, Streblina, Streptilon, Tartona, Tatina, Termontis, Trimista, Troxilanthes, Tulista, Tursitis, Vandera, Xamilenis, Zeliauros.

The following names have been published without description, so far as we have traced, by N. E. Brown in Gard. Chron. 78, 1925, key on 411 (all Aizoaceae): Argyroderma, Cephalophyllum, Conicosia, Conophytum, Cryophytum, Dactylopsis, Delosperma, Didymaotus, Disphyma, Ectotropis, Erepsia, Fenestraria, Frithia, Gibbaeum, Glottiphyllum, Hydrodea, Hymenogyna, Lithops, Macrocaulon, Malephora, Nananthus, Odontophorua, Oophytum, Opophytum, Phyllobolus, Platythyra, Pleiospilos, Prenia, Psilocaulon, Punctillaria, Rimaria, Sceletium, Semnanthe, Sphalmanthus, Synaptophyllum, Thyrasperma, Tricho-

cyclus, Zeuktophyllum.

KEY

TO THE FAMILIES OF

FLOWERING PLANTS

BASED ON ENGLER'S CLASSIFICATION AS GIVEN IN DIE NATÜRLICHEN PFLANZENFAMILIEN, AND REVISED IN HIS SYLLABUS, Ed. 7.

ii MONOCOTS. PANDANALES—TRIURIDALES A: a: β

MONOCOTYLEDONEAE

[Embryo with one cot.; stem with closed bundles; l. usu. #-veined; fl. usu. 3-merous.]

- A. Orders with predominant variability in number of floral parts (Orders 1—7):
 - a. Typically achlamydeous fls. appear (Orders 1-4).
 - a. Fls. usu. naked. Great variability in number of sta. and cpls.
- PANDANALES. Marsh herbs, or trees, with linear 1., and cpd. heads or spikes of naked, haplo- or homo-chlamydeous \$? fls. P bractlike, A ∞ 1. G ∞ 1. Endosp.
 - β. Naked fis. occur, but also all stages from achiam. to heterochiam. fis., and from hypog. to epig. Number of essential organs definite or not (Orders 2, 3).
- HELOBIAE. Water or marsh pl. with scales in axils, and cyclic or hemicyclic fis. P in o, 1, or 2 whorls, homo- or hetero-chlam., hypog. or epig. A ∞ — 1, G ∞ — 1, free or united. Endosp. little or none.
 - Potamogenonineae: fl. hypog., achlam., haplo-, or homochlam. (fams. 1—4).

- 2. Alismatineae: fl. hypog., usu. heterochlam.; ov. on ventral suture (fam. 5).
- 3. Butomineae: fl. hypog. or epig., usu. heterochlam.; ov. on inner surface of cpls. (fams. 6, 7).

٠,

3. TRIURIDALES. Saprophytes with scale 1. and small long-stalked homochlam. § or & § fis. P 3-8, valv., petaloid; & A 3, 4, or 6; § , 2 stds. G & each with I basal ov.; & styles. Pericarp thick. Endosp.

MONOCOTYLEDONEAE

T

 Typhaceae: rhiz. herbs with linear 2-ranked l. and cylindrical spikes of naked fis., ? below, & above; A 2-5, G 1 on hairy axis with 1 pend. ov.; nutlet, with album. seed.

Pandanaceae: woody pl., sometimes climbing, with 3-ranked 1. and term. or racemed spikes of ♂ ? fls., ♂ of ∞ sta. racemed or umbelled on short or long axis, ? of (∞ —1) cpls. with sessile stigs. and ∞ —1 ov.; heads of berries or drupes; endosp. oily.

Sparganiaceae: rhiz. herbs with 2-ranked l. and fis. in 3? heads,
 heads lower. P 3-6, sepaloid, A 3-6, G (1-2), each with
 pend. ov.; fr. drupaceous; endosp. floury.

2

- Potamogetonaceae: submerged or floating herbs of fresh or salt water, with usu. 2-ranked l. and sol. or spiked ? or ? s reg. fls. P usually o, A 4—1, G 4—1 each with 1 pend. ov.; fr. 1-seeded.
- 2. Najadaceae: submerged herbs with opp. linear toothed l. and 3? fls., 3 P 2, A 1 term.; ? P 1 or 0, G 1, with 1 basal anatr. ov.
- Aponogetonaceae: tuber-rhiz. water herbs with submerged or floating l. and spikes (in caducous spathes) of

 reg. fls. P 3—1 petaloid, A 3+2 or more, G 3—6; fr. leathery, seeds 2 or ∞, exalb.
- Scheuchzeriaceae: marsh herbs with narrow l. and racemes or spikes of \$\frac{1}{2}\$ or \$\sigma\$? reg. fls.; P usu. \$3+3, homochlam., bractlike, A \$3+3, G \$3+3 sometimes united, outer often absent, I or a anatr. ov. in each. [Lilaea \$\frac{1}{2}\$ start. A l. G l.]
 Alismaceae: water or marsh herbs with rad. l., latex, and much
- 5. Alismaceae: water or marsh herbs with rad. l., latex, and much branched infl. of reg. heterochlam. ¥ or & ? fls.; K 3, C 3, A 6—∞ or 3, G 6—∞ with t—∞ anatr. ov. and 6—∞ styles; no endosp.
- 6. Butomaceae: water and marsh herbs; latex; usu. = umbel-like cymose infl. of reg. usu. heterochlam. § fls.; K 3, C 3, A 9—∞. Q 6—∞, often united below, with ∞ ov. on inner surface; follicles.
- 7. Hydrocharitaceae: salt or fresh water pl. with alt. or whorled l. and sol. or cymose-paniculate fis. enclosed in 1 or 2 bracts, usu. heterochlam., reg., 3-merous, usu. 3?; A in 1—5 whorls, inner often stds., G (2—15), 1-loc. with parietal plac. and cov.; fr. irreg. dehisc. with co seeds. Exalb.

3

iv MONOCOTS. GLUMIFLORAE—FARINOSAE A; a; y; b; B; a

- y. Fls. usu. naked. Number of sta. rarely indefinite.
- 4. GLUMIFLORAE. Usu. herbs, with naked fis. (rarely with trichome-like or true P) covered by bracts (glumes). G 1-loc. with 1 ov.

- Fls. rarely naked, and then usu. by reduction, and accompanied by spathes of bracts; A and G commonly definite, but also frequently on sta. and > 3 cpls.
- 5. PRINCIPES. Tree-like or woody pl., sometimes climbing, with fan of feather l., and reg. usu. 3 ? fls. in spikes (usu. compound) or spike-like racemes, usu. in spathe; P 3+3, A 3+3, or 3, 9, or ∞, G 3 or (3), usu. with 1 ov. each; berry or drupe; endosp. rich.
- 6. SYNANTHAE. Often palm-like pl., climbers, or large herbs with \$\delta\$? fls. alternating over surface of spike, \$\delta\$ naked or with thick short P and 6—\$\ointimes\$ sta.; \$\delta\$ naked or with \$\delta\$ fleshy scaly P and long thread-like std. in front of each, G (2) or (4) with 2 or \$\delta\$ plac. and \$\infty\$ ov.; the r-loc. ovaries sunk in spike and united; multiple fr. with \$\infty\$ seeds: endosp.
- 7. SPATHIFLORAE. Herbs, or woody, sometimes climbing, rarely forming erect stem, usu. sympodial; fls. cyclic, haplo- or homochlam. or naked by abortion, 3—2-merous, § or & § often reduced to 1 sta. or cpl., in simple spikes (spadix), = enclosed in bract (spathe).
- 3. Fis. typically 5-cyclic, whorls typically iso-, usu. 3-merous, rarely more or 2-merous (Orders 8—11).
- a. Fls. homo- to hetero-chlam., rarely maked; P still often bract-like; hypogyny and actinomorphy the rule (Orders 8, 9).
- FARINOSAE. Usu. herbs, rarely with stout stem; fls. cyclic, homo- or hetero-chlam, 3—2-merous, usu. P 3+3, A 3+3, G (3), one whorl of A sometimes wanting, or all reduced to 1; ov. usu. orthotr.; endosp. mealy.
 - Flagellariineae: P homochlam., bracteoid, hypog.; ov. anatr. (fam. 1).
 - 2. Enantioblastas: P various, hypog.; ov. orthotr. (fams. 2-6).

4

I. Gramineae: herbs, rarely woody, with jointed stem and alt. 2-ranked l. with split sheath and ligule, and panicle or spike-like infls. of small y rarely d? naked fls. in spikelets, each beginning with I or more empty glumes, then paleae with axillary fls.; A usu. 3, G with I ov., micropyle facing down; stigs. 2, 3, or I; caryopsis with rich endosp.

Cyperaceae: herbs with usu. 3-angled stem and 3-ranked l. with closed sheath; fls. in spikelets or cymes united to large infls., naked, y or s ?; A usu. 3-1, G (3-2), styles 3-2, 1-loc.

with I basal anatr. ov.; nut; endosp.

5

1. Palmae.

6

1. Cyclanthaceae.

7

r. Araceae: tuberous herbs, sometimes woody, or lianes, with \$\fo\$ or \$\fo\$? fis. in same spike, often with spathe; fl. 2—3-merous or reduced to \$\tau\$ sta. or cpl.; fr. usu. berry; outer seed-coat fleshy.

2. Lemnaceae: free swimming water pl. usu. with no l. and naked & ? fls., & of I sta., ? of I cpl. with I—6 basal erect ov.; endosp. thin.

8

Flagellariaceae: pl. sometimes climbing, with long many-veined l. and small, \$ or \$? , 3-merous, reg. fis. in cpd. term. panicles;
 P bractlike, G (3) 3-loc. each with 1 ov.; fr. 3-loc. or with 3—1

stones; endosp.

2. Restionaceae: rush-like zero. or marsh herbs with creeping rhiz. and 2-ranked bracts or scale 1. on stem; fis. in spikes in axils of bracts, usu. d? reg.; P 3-2+3-2 sepaloid, A 3-2, G (3-1) with 3-1 styles, 3-1-loc. with 1 ov. in each; caps. or nut; endosp.

g. Centrolepidaceae: usu. marsh pl. with \bar{y} or \bar{s} ? fis., naked or with $i-\bar{g}$ hair-like br.; A $i-\bar{g}$ ($i-\bar{\infty}$) each with i pend ov.

vi MONOCOTS. FARINOSAE—LILIIFLORAE B; a

 Bromeliineae: P usu. heterochlam., hypog. to epig.; ov. anatr. (fams. 7—9).

- 4. Commelinineae: P heterochlam.; part of A often stds. or wanting (fam. 10).
- 5. Pontederiineae: P homochlam., petaloid, united (fams. 11, 12).
- 6. Philydrineae: P petaloid, the outer l. larger than inner, the 2 post. of outer whorl united, the post. of inner whorl aborted fam.

4. Mayacaceae: marsh pl. with alt. linear l. and sol. or umbelled greg. heterochlam. 3-merous fls.; K 3, C 3, A 3, G (3), style 1 with 3 stigs., 1-loc. with parietal plac. and few ov.: caps. 3-valved.

5. Xyridaceae: perenn. herbs with long narrow l. and axill. spikes of y heterochlam. 3-merous fls.; K-+ with 2 smaller lat. l., C (3) with tube, A 3 epipet., with sometimes 3 outer stds., G (3), 1-loc. with ∞ ov.; caps. 3-valved; endosp.

5. Eriocaulaceae: perenn. herbs with long linear l. and involucrate heads of fls. on long stalks, d ?, reg. or +, heterochlam., 2—3-merous, sta. usu. in 1 whorl, G (2—3), 2—3-loc. with 1 pend. ov. in each: caps.; endosp.

7. Thurniaceae: perenn. herbs with narrow l. and heads of ½, reg. homochlam. 3-merous fls. on Δ stalks; P 3+3, A 6, G (3),

3-loc. with 1-∞ ov. in each; caps.; endosp.

Rapateaceae: perenn. herbs with 2-ranked narrow 1.; infl. term. with 2 large spathes encl. head of spikelets, each of ∞ br. and term.

§ reg. 3-merous heterochlam. fl.; K (3), C (3), A 3+3, G (3), 3-loc. with ∞ —1 ov. in each; caps.; endosp.

Bromeliaceae: herbs, often epiph., with alt. usu. rad. l. and spikes or panicles of usu.

greg. heterochlam. 3-merous fls.; K 3, C or (C) 3, A 3+3, G (3), sup. to inf., 3-loc. with

ov.; herry or

caps.; endosp.

10. Commelinaceae: herbs with jointed stems, alt. sheathing 1. and cymes of blue or violet, \(\frac{\pi}{2} \) reg. or \(\frac{1}{2} \) heterochlam. 3-merous fls.; \(\text{K} \) 3, C 3, rarely united, \(\text{A} \) 3 + 3, \(\text{G} \) (3—2), style 1, 3—2-loc. with few ov.; caps.; endosp.

11. Pontederiaceae: water pl. often with 2-ranked l. and spicate § +fls.; P 3+3 with long tube, A 3+3, 3, or 1, on tube, G (3) with 1 style, 3-loc. with ∞ ov. or 1-loc. with 1; caps. or nut; endosp.

12. Cyanastraceae: herbs with tuber or rhiz. and raceme or panicle of greg. 3-merous fls.; (P) with short tube, A (6), G (3), with 1 style, 3-loc. with 2 ov. in each; caps. 1-seeded; perisp.

13. Philydraceae: herbs with 2-ranked narrow l. and spikes of homochlam. 3-merous ¥ + fis.; sta. 1 ant., G (3) with 1 style, 3- or 1-loc. with ∞ ov.; caps.; endosp.

9

Juncaceae: perenn. herbs with narrow usu. rad. l. and many-fld. infl. of homochlam. 3-merous ĕ reg. fls.; P sepaloid, A 6 or 3, G(3), style r with 3 stigs., r—3-loc. each with r—∞ ov.; caps.; endosp.

2. Stemonaceae: perenn. herbs with rhiz. and often climbing stem and axillary infis. of homochlam. § reg. 2-merous fis.; P sepaloid,

G(2), 1-loc.; caps.; endosp.

3. Liliaceae: herbs with rhiz. or bulbs, shrubs, or trees with infl. of usu. racemose type, of usu. homochlam. § reg. usu. 3-merous fls.; P or (P) 3+3, petaloid, A 3+3, Q to G 3—(2—5)-loc.; fr. various; endosp. fleshy or cartilaginous.

4. Haemodoraceae: perenn. herbs with 2-ranked 1. and simple or cpd. infl. of § reg. or + fis.; P 3+3, A 3, G to G, 3-loc. with

few ov.; caps,

viii MONOCOTS. LILIIFLORAE-MICROSPERMAE B; a; b

- 3. Iridineae: as last, but inner sta. aborted (fam. 9).
- b. Fls. homo-(petaloid) or heterochlam., epig., usu. + (Orders 10, 11).
- 10. SCITAMINEAE. Trop. herbs, sometimes very large or woody, with cyclic, homo- or hetero-chlam. usu. + 3 merous fls.; A typically 3+3, but often with great reduction, even to 1 sta., G usu. 3-loc. with large ov.; usu. aril, peri- and endosp.

- II. MICROSPERMAE. Fls. cyclic, homo-or hetero-chlam., 3-merous, typically diplostemonous, but commonly with great reduction in A, G 3- or 1-loc. with so small ov.; endosp. or o.
 - 1. Burmanniineae: fis. usu. reg.; endosp.
 - 2. Gynandrae: fis. always : no endosp.

- 5. Amaryllidaceae: herbs or shrubs of various habit and cymose infl. on scape, of \$\forall \text{reg. or } \dagger \frac{1}{18.} \dagger \frac{1}{2} + 3 \text{ petaloid, } A \frac{3}{4} + 3 \text{ usu. intr., often with stipular corona, } \overline{G}(3), \text{ rarely } \frac{1}{4} \div \text{inf., } 3 \div \text{loc. with } \infty \text{ ov.; caps. or berry.}
- 6. Velloziaceae: herbs or shrubs with linear crowded l. and term. sol. § reg. 3-merous fis. on long stalks; P petaloid, A 6 or 6 bundles, G (3), 3-loc. with ∞ ov. on lamellar plac.; caps.; endosp.

 Taccaceae: perenn. herbs with tubers and large entire or cymosely branched l., and cymose umbels of \$\frac{1}{2}\$ reg. fis. with long thread-like br.; P 3+3, petaloid, A 3+3, G (3), 1-loc. with parietal plac.,

6 petaloid stigs. and ∞ ov.; caps. or berry; endosp.

8. Dioscoreaceae: climbing herbs with usu. tuberous rhiz. and alt. or opp. often sagittate 1.; fis. in racemes, homochlam., § or & ?, reg.; P sepaloid, usu. united, with tube, A 3+3, inner sometimes stds., G (3), 3- or 1-loc., usu. with 2 ov. to each, styles 3 or 6; caps. or berry; endosp.

Iridaceae: perenn. herbs or undershrubs with equitant l. and term. cymose infl. of \$\forall \text{reg. or + fls.}; P 3+3 homo- or hetero-chlam., A 3 extr., \$\overline{G}\$ (3), 3-loc. with 3 styles sometimes divided and leafy.

ov. co, rarely 1-loc.; caps.; endosp.

IO

Musaceae: very large herbs with 'false' stem, or trees, with cpd. infl. with large often petaloid br. and \(\frac{1}{2} \) or \(\frac{2}{3} \) \(\frac{1}{3} \) homoor heterochlam. fls.; P 3+3, petaloid, often united, A 3+2 and std., \(\overline{G} \) (3), 3-loc. with 1-\infty ov. in each; berry or caps.; endosp. and perisp.

2. Zingiberaceae: perenn. herbs with tuberous rhiz. and lanc. petiolate l., with ligule and simple or cpd. infls. of usu. y .- fls.; K (3), C (3) forming tube below, A r (of inner whorl, with labellum opp. to it of 2 inner stds., and sometimes 2 outer stds.) G (3), usu. 3-loc. with ∞ ov.; caps.; usu. aril: endosp. and perisp.

3-loc. with ∞ ov.; caps.; usu. aril; endosp. and perisp.

3. Cannaceae: perenn. herbs with large 1. and cpd. infl. of showy heterochlam. § asymmetric fls.; K 3, C (3), A 1—5, only half of 1 inner sta. fertile, the other half, and rest, petaloid stds., G (3),

3-loc, with ∞ ov.; caps.; endosp, and perisp.

4. Marantaceae: perenn. herbs with 2-ranked 1. with pulvinus at end of stalk, and heterochlam. § asymmetric fis.; P 3+3, A 4-5, only 1 inner half fertile, as in last, the 2 other inner and 1-2 outer petaloid (1 inner usu. hoodlike), G (3), 3-loc. or 1-loc. by suppression, with 1 ov. in each; aril; caps.; endosp. and perisp.

II

Burmanniaceae: green or saproph. herbs with sol. or cymose fis.; P (3+3) or 3+3, A 3+3 or 3, G (3), 3- or 1-loc.; caps., ∞ seeds; endosp.

2. Orchidaceae: perenn. herbs of various form, often epiph. with pseudobulbs, and §, +, usu. resupinated, homo- or hetero-chlam. fis.; P 3+3, A 1 or 2, united with style of G (3) 1-loc. to form a column; pollen in tetrads usu. united to pollinia, stigmas 3, the third usu. rudimentary or forming a rostellum, ovules es; gaps; no endosp.

* DICOTS. VERTICILLATAE-JUGLANDALES A; B; a

DICOTYLEDONEAE

[Embryo with two cots.; stem with open bundles; l. usu. net-veined; fl. usu. not 3-merous.]

Archichlamydeae (Orders 1-30)

(Fl. achlam., haplochlam., or diplochlam., usu. polypet., rarely sympet. or apet.)

A. Ov. with 20 or more embryo sacs, and chalazogamic fert. (Order 1).

1. VERTICILLATAE. Woody pl. of Equisetum habit; & fis. in catkin-like spikes, ? in heads, at end of twigs; & with 2 median bractlike P and a central sta., ? naked, G (2) with 2 threadlike stigmas, 2-loc., the post. sterile, the other with 2-4 erect orthotr. ov.; fr. indeh.; no endosp.

B. Ov. usu. with only 1 embryo sac (Orders 2-30).

a. Fls. naked or with haplochlam, bract-like P (Orders 2-12). 2. PIPERALES. L. simple, stip. or not, and spikes of small achlam. or haplochlam. Y or & ? fls.: A 1-10, G 1-4, free or united.

3. SALICALES. Woody with simple alt. stip. 1. and spikes of dioec. achlam. fls., disc cup-like or reduced to scales; A 2-0, G (2), 1-loc. with parietal plac. and ∞ anatr. ov.; caps. with ∞ seeds, seeds small with basal tuft of hairs and no endosp.

4. GARRYALES. Woody pl. with opp. evergr. 1. and fis. in catkinlike panicles, & ?; & P 4, A 4, ? naked, G (2-3), 1-loc. with

2 ov.; endosp.

s. MYRICALES. Woody, usu. with simple I. and fis. in simple, rarely cpd. spikes, & ? achlam., sometimes with bracts at base; A 2-16, usu. 4, G (2), 1-loc. with 1 basal orthotr. ov. and 2 stigs.: porogamous; drupe with waxy exocarp; no endosp.

6. BALANOPSIDALES. Woody with simple 1.; & fis. in spikes, haplochlam, ? sol. surrounded by ∞ scaly bracts; G (2), im-

perfectly 2-loc. each with 2 ascending ov.; drupe.

7. LEITNERIALES. Woody with alt. entire l. and spikes of dioec. fis.; & achlam., A 3-12, ? haplochlam., P of small scaly united l., G I with long style and I amphitr. ov.; drupe; thin endosp.

8. JUGLANDALES. Woody with alt. usu. pinnate exetip. I. and spikes of achlam. or haplochiam. & ? fis.; A 3-40, G (2), 1-loc. with I basal orthotr. ov.; chalazogamic; fr. drupe or nut-like; no endosp.

DICOTYLEDONEAE

Archichlamydeae

Casuarinaceae.

Saururaceae: herbs with alt. l. and spikes of achlam.

fis.; A 6 or less, G(3—4) or 3—4, plac. parietal, ov. 2—∞; endo- and peri-sp.

I

 Piperaceae: herbs and shrubs with alt. l. of biting taste, and spikes, &c. of y or ♂ ? achlam. fls.; A 1—10, G(1—4), 1-loc. with 1 basal ov.; endo- and perisp.

 Chloranthaceae: herbs or woody pl. with opp. stip. l. and spikes or cymes of § or a § fis., sometimes with sepaloid P; A (1 or 3) united to ovary, G 1 with 1 pend. ov.; peri- and endosp.

Lacistemaceae: shrubs with 2-ranked lanc. exstip. l. and spikes of
minute # fls., naked or with sepaloid P; A 1, G (2-3) plac.
parietal, with 1-2 pend. ov. on each; caps. 1-seeded; endosp.

I. Juglandaceae:

xii DICOTS. BATIDALES—SANTALALES B; a; b

9. BATIDALES. Coast shrub with opp. fleshy l. and panicles of spikes; fls. \$?, \$\delta\$ with cup-like P and A4, \$? naked, originally 2-loc. with 2 ov. in each, divided by false septum, all \$ fls. in spike concrescent; aggregate fr.; no endosp.

10. JULIANIALES. Woody with alt. usu. pinnate exstip. 1. and dioec. fls.; ∂ ∞ in ± dense panicle, P, A, 6—8, ? in fours at end of downward directed spike, naked, G 1-loc. with 1 ov. on broad

hollowed funicle; no endosp.

11. FAGALES. Woody with alt. stip. l. and fis. in simple or cymose spikes, cyclic, homochlam., rarely naked, usu. monoec.; A opp. P, G (2-6) each with 1-2 ov.; fr. nut-like, seed 1; no endosp.

12. URTICALES. Herbs, shrubs, trees with alt. or opp. stip. l. and cymose infis. of cyclic homochlam. rarely haplochlam. or naked usu. reg. § or & § fis., usu. 2+2 rarely 2+3-merous; sta. before P, Q (2—1) with 1 ov.; drupe or nut.

- b. Usu. with sepatoid or petatoid P, rarely heterochlam. (Orders 13-16).
- 13. PROTEALES. Woody with alt. exstip. 1. and spikes or racemes of cyclic homo- (apparently haplo-)chlam. 2+2-merous y or σ ? reg. or + fls.; P petaloid; sta. anteposed and usu. adherent to P, G τ; fr. various, no endosp.
- SANTALALES. Herbs, shrubs, trees, often paras., with cyclic, usu. homochlam. fls.; A anteposed, in 1 or 2 whorls, G, rarely G (2-3), rarely 1, each with 1 pend. ov. (or ov. not differentiated).
 Santalineae: ov. differentiated from plac., often without integ. (fams. 1-6).

9

z. Batidaceae:

IO

I. Julianiaceae:

II

Betulaceae: shrubs and trees with alt. simple l. with caducous stips.
 and monoec. anemoph. fis. in catkins, typically 3 fis. per axil;
 P sepaloid or o, A 2—10, G (2), 2-loc. each with 1 pend. ov.;
 nut; no endosp.

Fagaceae: trees, rarely shrubs, with simple l. and caducous scaly stips., and usu. catkins or small spikes of c? fls.; P sopaloid (4—7), A 4—7 or 8—14, G usu. (3), 3-loc., 3-styled, each with 2 pend. ov.; nut; no endosp.

12

Ulmaceae: trees and shrubs with 2-ranked simple stip. I. and axill.
cymes of homochlam. § or 3 ? fls.; P 4—5, sepaloid, A 4—5 or
8—10, G (2), styles 2, usu. 1-loc. with 1 pend. ov.; nut or drupe;
usu. no endosp.

 Moraceae: usu. trees and shrubs with stip. 1., latex, and cymes of small 3? fls., often head-like; P usu. 4 or (4), persistent, rarely o, A as many, opp. P, G (2), 1-loc. with usu. 1 pend. ov.; nut or drupe; endosp. or not.

3. Urticaceae: usu. herbs with opp. or alt. stip. 1., no latex, and cymose infls. of small homochlam. usu. 3 ? fls.; P usu. 4—5, A 4—5 opp. P, bent inwards in bud and exploding, G 1-loc. with 1 basal ov. and 1 style; nut or drupe; endosp.

13

1. Proteaceae:

14

 Myzodendraceae: semiparas, undershrubs with alt. 1. and minute naked 3 ? fis.; A 2-3-1 with monothecous anthers, G (3) with axile plac. and 3 ov.; fr. with 3 feathery bristles in angles.

s. Santalaceae; semiparas. herbs, shrubs, trees with opp. or alt. l. and small & or & ? homochlam. fls. with perig. or epig. disc; P usu. s+2 or s+3, A as many, inserted on P, G 1-loc. with axile placand 1—3 ov.; nut or drupe, 1-seeded; endosp.

xiv DICOTS. SANTALALES—CENTROSPERMAE B; b; c

- 2. Loranthineae: ov. usu. not differentiated (fam. 7).
- Balanophorineae: plac. central with pend. ov. with no integ.; chlorophyll-less paras. (fam. 8).
- 15. ARISTOLOCHIALES. Fls. cyclic, homo- or haplo-chlam, reg. or +; P petaloid, G usu. inf. 3—6-loc. with axile plac., or 1-loc. with parietal, and ∞ ov.

- 16. POLYGONALES. L. usu. ochreate, fls. haplo- to hetero-chlam., # reg.; G 1-loc. with usu. 1 basal erect ov.; nut; endosp.
 - P haplochlam., sepaloid or petaloid, sometimes heterochlam. (Order 17).
- CENTROSPERMAE. Usu. herbs with spiral or cyclic homoor hetero-chlam. fis.; A usu. = and opp. P, but also ∞ —1, G (∞ —1), or free, rarely G, usu. 1-loc. with ∞ —1 campylotr. ov.; perisperm.
 Chemopodinase: P bracteoid, not > g, A anteposed; ovule usu. 1 (fams. 1, 2).

3. Opiliaceae: fis. # heterochlam. with slight seam-like K; \$\overline{G}\$ with 1 ov. with no integument.

4. Grubbiaceae: trees or shrubs with opp. leathery l. and small \(\frac{1}{2}\) reg. fls.; P 4 sepaloid, A 4+4, \(\overline{G}\) (2), 2-loc. below when young, later 1-loc. with 2 pend ov. on central plac.; drupe; oily endosp.

5. Olacaceae: trees and shrubs with usu. alt. entire 1. and small y reg. fls.; K 4-6, very small, C 4-6, A as many or 2-3 times as many, G (2-5), 2-5-loc. at base, 1-loc. above, with 1 ov. pend. into each loc.; 1-seeded drupe or nut; endosp.

6. Octoknemataceae: woody with alt. l. and & fis.; P 2+3, A 2+3,

anteposed, G 1-loc. with 3 pend. ov.; drupe 1-seeded.

Loranthaceae: woody semiparas., usu. on trees, with usu. reg. 2—3-merous, usu. homochlam. § or 8 ? fls.; P in two whorls, A as many, G 1-loc. usu. without differentiation of ov. and plac.; layer of viscin round seed; endosp.

8. Balanophoraceae: fleshy root paras. with tuberous rhiz. from which stems rise endog., and small fls. in spikes or heads, homochlam. or naked, usu. 6 ?; P in 6 3—4 (2—8), united below, A as many or 1—2; P in ? usu. 0; G (1—2), rarely (3—5); nut or drupe;

endosp.

15

Rafflesiaceae: thalloid parasites, shoots very short with term. fl. or raceme, usu. s?, reg. haplochlam.; P (4—5), A ∞ on column, G (4—6—8) with parietal plac. or ∞ twisted loc.; berry with

oo seeds; endosp.

Hydnoraceae: thalloid paras. with \$\forall \text{ reg. fls.}; P (3-4), fleshy,
 A 3-4, epiphyllous, G (3) with parietal. plac. and \$\infty\$ ov.;
 berry; endo- and perisp.

16

1. Polygonaceae:

17

I. Chenopodiaceae: usu. herbs with alt. often fleshy l. and cymose infis. of small reg. homochlam. § or \$2 fls.; P (5) or less, imbr. sepaloid, A as many, anteposed, bent inwards in bud, G (2) I-loc. with I basal ov.; nut; endosp.

s. Amarantaceae: herbs or shrubs with opp. or alt. exitip. l. and small haplochlam. usu. \(\foating \text{reg. fls. in cymose or cpd. infls.; P 4-5 or (4-5) usu. sepaloid, A 1-5 anteposed and \(\text{\upsa} \) united below.

G(3-3), 1-loc. with $\infty-1$ ov.; nut; endosp.

xvi DICOTS. CENTROSPERMAE—RANALES B; c; d; a

Phytolaccineae: P haplo- to hetero-chlam., tending to cyclic; A sometimes ∞, G sometimes little united (fams. 3—6).

- 3. Portulacineae: P heterochlam.; K 2, C 4-5 (fams. 7, 8).
- Caryophyllineae: P heterochlam., K=C; fl. cyclic, sometimes with no C (fam. 9).
- d. Fls. usu. heterochlam. (Orders 18-30).
 - a. Apocarpy and hypogyny the rule; perig. and epig. fis. only in Lauraceae and Hernandiaceae (Order 18).
- 18. RANALES. Herbs or woody pl. with spiral, spirocyclic, or cyclic, usu. haplo- or hetero-chlam. rarely achlam. reg. or ·|· fis.; A usu. ∞, G ∞ —1, rarely united.
 - 1. Nymphaeineae: fls. various, usu. spiral; ov. (exc. in 2)
 usu. ∞ on inner surface of cpls.; mostly water plants
 (fams. 1, 2).
 - Trochodendrineas: fis. naked, spirocyclic; ov. on ventral suture; no oil cells (fams. 3, 4).
 - g. Ranunculineas: fis. with P, spiral to cyclic; ov. on ventral suture; no oil cells (fams. 5—8).

NYCTAGINACEAE—BERBERIDACEAE xvii

3. Nyctaginaceae: herbs or woody, with opp. exstip. 1. and cymose \$ or \$\delta\$ or greg. fls. with bracts, sometimes united or petaloid, at base; P (5) petaloid, lower part persistent on fr.; A typically 5 (1—30), \$\overline{G}\$ 1 with 1 basal erect ov.; achene; perisp.

4. Cynocrambaceae: herbs with fleshy stip. 1., the lower opp., and & ? fls., & P 2-5, A 10-30, ? P (3-4), G 1, 1 ov.; drupe; endosp.

Phytolaccaceae: herbs or woody, with racemes or cymes of reg. usu. § fls.; P usu. 4—5, A 4—5 or ∞, G (rarely G) 1—∞, free or united, 1 ov. in each; drupe or nut, rarely caps.; perisp.

6. Aizoaceae: herbs or undershrubs with threadlike or fleshy opp. or alt. exstip. 1. and cymose infls. of § reg. fls.; P 4—5 or (4—5), A 5 (3—∞), the outer petaloid stds., G or G (2—∞) with ∞ ov., usu. 2—∞-loc.; caps.; perisp.

Portulacaceae: herbs or undershrubs with fleshy l. and often hair-like stips., and cymes of reg.

 § fls.; K usu. 2, C 4—5, A 5 or 5+5, or fewer or ∞, G or semi-inf. (3—5) 1-loc. with 2—∞ ov. on basal plac.; caps.; endosp.

Basellaceae: twining herbs with a reg. fls.; K 2, C 5 united below, A 5 anteposed, G (3), 1-loc. with 1 basal ov.; nut; endosp.

Caryophyllaceae: herbs or undershrubs with entire usu. opp. l. and cymose panicles of usu. reg.

fls.; K 5 or (5), C 5 or 0, A 5 or 10, G (5-2), I-loc. usu. with free-central plac., ov. 1—∞; caps. or berry; endosp.

18

- Ceratophyllaceae: submerged water pl. with whorls of 4 l. and sol.

 a saxillary reg. fls.; P 9—12 sepaloid, A 12—16, G 1 with 1 pend. ov.; nut; endosp.
- 3. Trochodendraceae: woody with alt. exstip. l. and sol. or racemed naked g or 3 ? fls.; A ∞ , G 5— ∞ with ∞ —s ov.; endosp.
- 4. Cercidiphyllaceae: woody with opp. stip. l. and sol. dioec. fis.;
 A ∞ spiral, G 2—5, stalked, with ∞ ov.; follicles; endosp.
- Ranunculaceae: usu. herbs, often with divided l. and usu.

 ÿ reg.
 rarely + or fully cyclic fls.; P often haplochlam., usu. petaloid,
 rarely K, C, A usu.
 ω ω σ ω rarely united, with ∞ I ov.;
 follicle or caps., rarely berry; endosp. oily.

6. Lardizabalaceae: climbing shrubs with cpd. l. and sol. or racemed # or \$ reg. fls.; P 3+3 usu. with two whorls of honey-l., A 3+3, G 3 or more with ∞ ov.; berry; endosp.

7. Berberidaceae: herbs or shrubs with simple or cpd. l. and ? reg. homo- or hetero-chlam. 3—2-merous fis.; P in 2—4 whorls, often with 2 whorls of honey-l., A in two, G I, rarely more, with 60—1 ov.; berry; endosp.

G (3-5) with parietal or axile plac. and 3-∞ ov.; endosp.

y. Apocarpy and hypogyny occur, but perigyny is commoner;

syncarpy and epigyny also common (Order 21).

21. ROSALES. Fl. cyclic, rarely spirocyclic, heterochlam. rarely apet., hypog. to epig., reg. or +; G or (G) sometimes with thick plac. and ∞ ov.

 Podostemonineae: submerged trop. water pl. of alga or lichen-like form (fams. 1-3).

 Saxifragineae: G=or fewer than C; endosp. usu. rich (lams. 4-13). Moringaceae: trees with pinnate exstip. l. and panicles of \(\frac{1}{2} \) + fls.; K, C, A 5, and 5 stds., G (3) on short gynophore, with parietal plac. and cov.; caps.; no endosp.

- Sarraceniaceae: herbs with pitcher l. and scapes with sol. or racemed $\frac{1}{2}$ reg. fls.; K 8-5, C 5, A ∞ , G (5-3) 5 or 3-loc. with co ov.; caps.; endosp.
- Nepenthaceae: climbers with alt. l., the lower with pitchers, the upper tendrilled, and racemes or panicles of & ? reg. fls., P 2+2 homochlam., A (4-16), G (4), 4-loc. with ∞ ov.; caps.; endosp.
- Droseraceae: herbs usu. with alt. l., usu. rolled in in bud, and with sticky glands, and cymose & reg. fls.; K, C 5-4, A 5-4-20, G (5-3), 1-loc. with ∞ -3 ov.; caps.; endosp.

21

- 1. Podostemaceae: herbs (usu. trop.) of rushing water with reg. or + y achlam. fls.; A ∞ -1 free or united, G(2), 2-1-loc. with thick central plac. and co or few anatr. ov.; caps.
- Tristichaceae: as last, with reg. or slightly + homochlam. \forall fls.; P 3-5 sepaloid, A as many, or 4-5 times as many, or 2-1, G (2-3), 2-3-loc. with ∞ ov. on thick central plac.; caps.
- Hydrostachyaceae: herbs (S. Afr.) of running water with spikes of 3∙
- dioec. naked fls.; s of 1 sta., s of (2) cpls. with ∞ ov.; caps. Crassulaceae: succulent exstip. herbs or undershrubs, usu. with cymose infl. of reg. \$3-30-merous fls.; C or (C), A obdipl. or in one whorl, G sometimes slightly united, with ∞ ov.; follicles: endosp.
- Cephalotaceae: perenn. herbs with some pitcher 1. and panicles of reg. fls.; P 6, A 6, G 6 with 1-2 basal ov.; follicles; endosp.
- Saxifragaceae: herbs, shrubs or trees with usu. alt. l. and various infl. of usu. ∞ ¥ reg. (rarely +) fls. with convex, flat or concave axis; A usu. obdipl. or = C, G = C or less, with usu. free styles, 2—t-loc. (rarely 5) with swollen plac. and ∞ ov. in several ranks, sup. or inf.; caps. or berry; endosp.
- Pittosporaceae: woody, sometimes climbing, with alt. l. and resin 7. passages, and \(\frac{1}{2} \) reg. 5-merous fls.; \(\frac{G}{2} \) (2 or more) 1—5-loc. with parietal or axile plac. and 2-ranked on anatr. ov., and simple style; caps. or berry; endosp.
- Brunelliaceae: woody with opp. or whorled I. and panicles of small 8 4-5-7-merous diplost. fls.; K. valv., Co, G 5-2 each with a pend. ov.; follicle-caps.; endosp.
- 9. Cunoniaceae: woody with opp. or whorled stip. 1.; like 6, but ov. in 2 ranks.
- 10. Myrothamnaceae: small shrubs with opp. fan-folded l. and spikes of & ? reg. achiam. fis.; A 4-8, G (4-3); caps. septicidal; endosp.

xxii DICOTS. ROSALES—GERANIALES B; d; y; 8

3. Rosineae: $G \infty - 1$; ov. with 2 integ.; endosp. little or o (fams. 14-18).

 Fis. usu. with 5 or 4 whorls; apocarpy and isomery appear, but syncarpy and oligomery of G are the rule (Orders 22—26).

22. PANDALES. Fls. cyclic, heterochlam., dioec. G (3), each with 1 pend. orthotr. ov.; drupe.

23. GERANIALES. Fis. cyclic, heterochlam., apet. or naked, usu. 5-merous; A various, G (5-2), rarely more, often separating when ripe, usu. with 2-1 rarely ∞ ov., pend. with ventral raphe and micropyle up, or when > 1 present, some with dorsal raphe and micropyle down.

E. Gerantineae: fis. heterochlam. rarely apet., usu. reg. and obdipl., rarely haplostemonous and in it fis. usu. abortion of some sta.; anthers opening longitud., G iso- or oligo-merous; ov. with 2 integ. (fams. 1-12).

A. No secretory cells or passages (fams. 1-7).

- 11. Bruniaceae: heath-like undershrubs with alt. exstip. î. and cpa. spikes, racemes and heads of usu. reg. and perig. § fls.; K, C, A 5, G (3-2) each with 3-4 ov. or 1 with 1; caps.; aril; endoso.
- 12. Hamamelidaceae: woody with usu. alt. stip. l. and spikes or heads of \(\for \sigma \) reg., heterochlam. apet. or naked fls. surrounded by br.; K, C, A 4—5, G (2) with r—∞ pend. ov.; caps.; endosp.
- 13. Eucommiaceae: trees with alt. extip. l. and latex, and naked of reg. fls.; A 6—10, G (2), one aborting, with 2 pend. ov.; samara; endosp.
- 14. Platanaceae: woody with alt. 3—5-lobed stip. l. and pend. spherical heads of \$? reg. fls.; K, C, A 3—8, G usu. 1, free, with 1—2 ov.; caryopsis; endosp.
- Crossosomataceae: shrubs with small stiff grey-green l. and sol. fls.; like Rosaceae-Spiraeoideae, but seeds kidney-shaped; aril; endosp.
- 16. Rosaceae: herbs, shrubs, or trees with usu. alt. stip. l. and reg. (rarely +) 5 (3—8 or more)-merous fls.; axis flat or hollowed; K 5, C 5 or o, A 2—4 or more times as many, bent inwards in bud, G=K or 2-3 times as many, or ∞, rarely 1—4, free or united to hollow axis, usu. 1-loc. with 2 ov. per cpl.; follicle, achene, drupe or pome; endosp. thin or o.
- 17. Connaraceae: usu. climbing shrubs, rarely trees, with alt. exstip. l. and panicles of reg. § or & § fis.; K 5 or (5) persistent, C 5, A 5+5, G usu. 5, rarely 4 or 1, each with 2 ov.; one follicle with 1 seed; aril; endosp. or none.
- 18. Leguminosae: trees, shrubs, or herbs, usu. with alt. stip. l. and racemes of reg. or + usu.

 § fls.; K, C 5, A 5 + 5 or more, G usu.

 1, rarely 2-5-15, with ∞ ov.; pod or indeh. fr.; endosp. usu.
 none.

22

1. Pandaceae.

23

- Geraniaceae: herbs with lobed or divided l., stip. or not, and § usu.
 reg. 5-merous fis.; A 10—15, sometimes only 5 fertile, G (5—2)
 usu. with 1—2, rarely 2—∞ ov. per cpl.; schizocarp, rarely caps.;
 endosp.
- Oxalidaceae: usu. herbs with alt. cpd. stip. or exstip. l. and ¥ reg. 5-merous fis. with no disc; A 10 obdiplost., united at base, G (5) with ∞ —1 ov.; caps. or berry; endosp.

B. Secretory cells or passages (in 10 sometimes only in pith and bark) (fams. 8—12).

Malpightineae; as last, but fis. obliquely +, at least in G;
 l. often opp. (fams. 13—15).

3. Tropaeolaceae: usu. climbers with sensitive petiole, stip. or not, and \$ 5-merous - fis., with axis prolonged into post. spur; A 8, G 3-loc. with 1 ov. in each; schizocarp; no endosp.

Linaceae: herbs or woody with alt. l., stip. or not, and \$ reg. 5-4-merous fls. with no disc; A 5-20 united below, G 5-4 (or less)-loc. with 1-2 ov. in each and often with extra partitions; caps. or drupe; endosp.

Humiriaceae: woody with alt. stip. l. and reg. § 5-merous fls. with cup-shaped disc; A 10-∞, G (5) each with 1-2 ov.; drupe.;

endosp.

Erythroxylaceae: woody with alt. simple stip. l. and 5-merous & reg. fls., heterostyled with no disc; C with appendages on inner side, A 10, united in tube at base, G (3-4), 3-4-loc, but only 1

fertile, with 1-2 ov.; drupe; endosp.

7. Zygophyllaceae: usu. shrubby with opp. often pinnate stip. l. and cymes or cpd. infls. of reg. \$ 5-4-merous fls. with disc or gynophore; A 10-8, rarely 15, often with united basal appendages. G (5-4) or more with 1-∞ ov.; usu. caps. or schizocarp; endosp. or o.

8. Cneoraceae: shrubs with alt. narrow leathery exstip. 1., oil cells. and single or cymose reg. ₹ 3-4-merous fls. with disc; A 3-4.

G (3-4), lobed, each with 2 ov.; style 1; schizocarp.

Rutaceae: usu. woody with alt. or opp. simple or cpd. exstip. 1. and reg. or | usu. \$5-4-merous fis. with disc; A obdipl. or 5-4-3-2, rarely ∞ , G(5-4) rarely $(3-1 \text{ or } \infty)$ with $\infty-2 \text{ ov.}$; fr. various; endosp. or none.

10. Simarubaceae: woody pl. with bitter bark, alt. or opp. usu. pinnate exstip. I. and reg. usu. & ? 5-4-merous fls. with disc; A 10,

5, or ∞, G (5) or less; fr. various; endosp. thin or none.

11. Burseraceae: woody pl. with alt. usu. cpd. l., resin-passages and small reg. usu. 3 25-4-merous fis. with disc; A obdipl. or 5, G (5-3) each usu. with 2 ov.; style 1; drupe or caps.; no endosp.

12. Meliaceae: woody pl. usu. with pinnate exstip. l. and usu. § reg. fis. in cymose panicles; axis rounded or with effigurations; K. C sometimes united, A usu. in tube, obdipl. or 5, G (5) or less, multi-loc. with 1-2 rarely more ov. in each, and I style; fr.

various: endosp. or o.

13. Malpighiaceae: woody usu. climbing pl. with opp. stip. l. and g obdipl. 5-merous fis. with convex or flat axis, sometimes with gynophore; K (5), often with nectaries, C 5 usu. clawed, A 5+5, often some aborted, G usu. (3), each with 1 ov.; schizocarp, nut or drupe; no endosp.

14. Trigoniaceae: woody often climbing pl. with alt. or opp. l. stip. or not and wobliquely + 5-merous fis.; K (5), C 5-3 often very unequal, A 5-6-10, ±united in tube at base, G (3) with ∞-

2 ov. each; caps.; endosp. or not.

15. Vochysiaceae: woody, rarely herbs, with opp. or whorled simple L, stip. or not, and v obliquely + fls.; K (5), one often spurred, C usu. 3-1, perig. or epig., A 1 and stds., G or G (3) each with so -- s ov.; fr. indeh. or caps.; no endosp.

kxvi DICOTS. GERANIALES—SAPINDALES B: d: δ

- 3. Polygulineas: fis. reg. or ... with two whorls of sta.; anthers opening by pores, G (2), median (fams. 16, 17).
- 4. Dichapetalineae: fls. reg. or : with 1 whorl of sta.; C or (C), ov. with 1 integ., seed sometimes with caruncle (fam. 18).
- 5. Tricoccae: its. reg. & ? often much reduced; G (3) each with 2-1 ov. with 2 integ.; usu. caruncle (fam. 19).
- 6. Callitrichineae: herbs, often submerged, with crowded l. and small axillary monoec. naked fls.; 3 with term. sta., ? with 2 transv. cpls. divided into 4, with 1 ov. in each section; fr. of 4 nutlets; endosp. (fam. 20).
- \$4. SAPINDALES. Usu. woody; as last, but ov. in reversed position, pend. with dorsal raphe and micropyle up, or erect with ventral raphe and micropyle down.
 - 1. Buxineae: haplochlam.; ov. with 2 integs. (fam. 1).
 - 2. Empetrineae: heterochlam., cpls. each with 1 erect ov. with 1 integ., united till ripe; shrubs (fam. 2).
 - Coriariineas: heterochlam., cpls. each with 1 pend. ov. with 2 integ., finally free; shrubs (fam. 3).
 - 4. Limnanthineae: heterochlam., cpls. each with 1 erect ov. with 1 integ., finally free; herbs (fam. 4).
 - Anacardiineae: heterochlam., rarely apet., reg.; G usu. oligomerous; woody with resin passages (fam. 5).
 - Celastrineae: fis. heterochlam., reg., with 2 or 1 whorls of A; G most often oligomerous (fams. 6—14).

TREMANDRACEAE-CORYNOCARPACEAE xxvii

16. Tremandraceae: shrubs with entire or toothed I. and sol. axillary 4—5 (rarely 3)-merous & reg. fls.; K free, C valv., A in 2 whorls, G (2) with 1—2 ov. each; caps.; endosp.

17. Polygalaceae: herbs, shrubs, or trees with sim le entire usu, alt. exstip. l. and racemes, spikes, or panicles of \$ 1. fls.; K usu. 5, 2 larger and petaloid, C 3, 1 often keel-like, A (4+4) or fewer, usu. united below, G usu. (2), 2-loc. with 1 ov. in each; caps. nut or drupe; endosp. or o.

18. Dichapetalaceae: woody, often lianes, with entire stip. 1. and small g or o g usu. reg. fls. with disc or scales; K 5 or (5), C 5 or (5), often forked, A 5, sometimes united to C, G (2-3) each with

2 ov.: drupe; no endosp.

10. Euphorbiaceae: herbs, shrubs, and trees, usu. with alt. often stip. I., often latex, and cpd. infls. of a ? reg. usu. 5-merous fls.; P usu. in 1 whorl, or 0, A 1-∞ free or united or branched, Gusu. (3), 3-loc. with 2-lobed styles, and 1-2 pend. anatr. ov. in each, with ventral raphe and micropyle usu. with caruncle; usu. schizocarp-caps.; endosp.

20. Callitrichaceae:

Buxaceae: woody pl. with entire evergr. exstip. 1. and reg. & ? apet. or naked fls., sol. or in racemose infls.; $A_4 - \infty$, $G_{(3)}$ or (2-4)each with 2-1 ov.; caps. or drupe; endosp.

Empetraceae: ericoid shrubs with linear exstip, grooved l. and heads of small & ? reg. fls.; K, C, A 2-3, G (2-0): drupe; no

caruncle.

Coriariaceae: woody pl. with opp. or whorled exstip. l. and axillary or racemed \(\text{or } \delta \) reg. fls.; K, C 5, A 5 + 5, \(\overline{G} \) 5-8; schizocarp,

Limnanthaceae: annuals with alt. exstip. l. and sol. axillary & reg. 5-3-merous fls.; K, C, 5-3, A 10-6, G(5-3), with 1 ov. in

each, separating when ripe; no endosp.

Anacardiaceae: woody pl. with alt. exstip. not gland-dotted l. and co fls. in panicles, typically 5-merous, hypog. to epig.; A 10-5 or other number, G (3-1) rarely (5), each with 1 anatr. ov., often only one fertile; drupe, no endosp.

6. Cyrillaceae: woody pl. with evergr. l., and racemes of small & reg. 5-merous fls.; K, C sometimes united, A in 2 whorls, G (5-2)-loc. each with 1 ov.; endosp.

Pentaphylacaceae: woody pl. with alt. leathery l. and small & reg. fls. in racemes below 1.; K, C, A 5, G (5) each with 2 pend. ov.; caps.: endosp.

8. Corynocarpaceae: woody pl. with alt. leathery l. and small # fis. in panicles; inner sta. stds., G (2), I fertile with I pend. ov.; drupe; no endosp.

- 7. Icacinineae: fis. heterochlam. reg. with 1 whorl of stabefore K; G usu. 1, integ. 1, fr. 1-seeded (fam. 15).
- Sapindineas: fls. heterochlam., typically with 2 whorls of sta, but with aborted sta. and cpls., reg. or obliquely +; ov. with 2 integs. (fams. 16—18).

- 9. Sabiineae: fis. heterochlam., sta. besore pets. (fam. 19).
- Melianthineae: fis. heterochlam., +, with 1, rarely 2, whorls of sta. with free anthers (fam. 20).
- 11. Balsaminineas: as last, but anthers united (fam. 21).

Aquifoliaceae: woody pl. with alt. evergr. simple l., stips. small or none, and dioec., reg., 4—more-merous &? fls. in cymose umbels; K, C 4, A 4 often epipet., G (4—6) or more, each with 1—2 pend. ov.; drupe with several stones; endosp.

10. Celastraceae: woody pl. with simple opp. or alt. 1., sometimes stip., and small

greg. 4—5 merous fls. in cymose umbels; A 4—5 on edge of disc,

G(2—5) each with ∞—1 ov.; caps. or berry;

often aril; endosp. or not.

11. Hippocrateaceae: woody pl., often climbing, with opp. or alt. simple l., stips. small or none, and small, y reg. fls. in cymose umbels; K, C 5, A 3, rarely 5, G (3) each with ∞ -2 ov.; berry or 3-winged fr.; no endosp.

12. Salvadoraceae: woody pl. with opp. simple l. and sometimes bristle-like stips., and panicles of \(\begin{align*} \text{or } d \(\begin{align*} \text{reg. fls.; } K (4-2), \ C4-5 \text{ or } (4-5), A 4-5, \(\overline{G} \) (2), \(1-2\)-loc. with \(1-2\) basal ov. in each; berry or drupe, usu. 1-seeded; no endosp.

 Stackhousiaceae: herbs with alt. exstip. l. and spikes or cymes of fl.; K, C, A 5, G (2-5)-loc. each with 1 erect ov.; schizocarp;

endosp.

14 Staphyleaceae: woody pl. with opp. lobed stip. 1. and panicles or racemes of fls.; K, C 5, A 5, outside disc, G (2-3), free above with ∞—few pend. ov.; caps.; endosp.

15. Icacinaceae: woody pl. some climbing, usu. with alt. exstip. l. and small \(\) or \(\) \(\) reg. fls.; K, C, A 5-4, \(\) (3), usu. 1 only with

2 pend. ov.; drupe; endosp.

16. Aceraceae: trees with opp. exstip. l. and small reg. y & \$ fls. in spikes, racemes or panicles; axis disc-like or concave; K, C, A 4—10, G (2) each with 2 ov.; fr. with 1-seeded samaras; no endosp.

17. Hippocastanaceae: trees with opp. palmate exstip. 1. and cymose racemes of $\{\cdot\}$ of $\{\cdot\}$ fis.; K (5), C 4—5, A 5—8, G (3)-loc. each

with 2 ov.; caps. 3—1-loc. usu. 1-seeded; no endosp.

18. Sapindaceae: woody pl. with alt. l. and usu. 4 y σ s fls. with extrastaminal disc; K 5, C 5—3 or o, often with scales, A usu. 8, rarely 10, 5, or ∞, G (2—3) each usu. with 1 ov.; caps., drupe, nut, or schizocarp; no endosp.

19. Sabiaceae: woody pl., often climbers, with alt. exstip. l. and small § or § 6 ? fis. in racemes or cymose racemes; K (2—5), C 4—5, A 5 antepetalous, G (2—3) each with 2 ov.; fr. 1-loc., 1-seeded;

no endosp.

20. Melianthaceae: woody pl, with alt. usu. pinnate l., stip. or not, and racemes of y + fls.; K, C 5, A 5—4, rarely 10, unequal or partly united, G (4—5) each with ∞ —1 ov.; caps.; aril or not;

endosp.

21. Balsaminaceae: herbs with watery translucent stems and alt. usu. exstip. 1., and # + fis.; K 5, the 2 ant. often small or aborted, C 5, the lat. ones united in pairs, A (5), G (5)-loc. each with ∞ ov.; caps. usu. explosive; no endosp.

xxx DICOTS. RHAMNALES—PARIETALES Β; d; δ; «

25. RHAMNALES. Fl. cyclic, diplochlam., sometimes apet., with
1 whorl of sta. before pets., reg.; G (5-2) each with 1-2
ascending ov. with dorsal, lat., or ventral raphe and 2 integs.

26. MALVALES. Fl. cyclic, exc. sometimes the A, heterochlam., rarely apet., usu. § and reg.; K, C usu. 5-merous, K usu. valv., A ∞ or in 2 whorls, the inner branched, G (2—∞) each with 1—∞ anatr. ov. with 2 integs.

 Elaeocarpineas: K = free, anthers dithecous with pores; no mucilage cells (fam. 1).

- Chlaenineae: K free, imbr., A enclosed by a cup, anthers
 dithecous with slits; mucilage cells often present
 (fam. 2).
- 3. Malvineae: K rarely imbr., usu. valv.; mucilage cells (fams. 3-7).

4. Scytopetalineae: seps. united into dish-like K (fam. 8).

c. Fis. spirocyclic or in 8—4 whoris; apocarpy only in lower forms, syncarpy the rule, often with a sinking of G in axis (Orders 27, 22).

 PARIETALES. Fl. spirocyclic or cyclic, often A and G ∞, heterochlam., rarely apet., hypog. to epig.; G = united, often with parietal plac. which may touch in centre, very rarely with basal ον.

 Theineas: G free on convex or flat axis; endosp. oily (fams. 1—9). Rhamnaceae: woody pl., rarely herbs, often climbing, with simple strp. l. and small greenish or yellowish fls. often in axillary cymose infls.; K 5-4, C 5-4 small, or o, A 5-4, G to G (5-2) with 1 ov. in each; dry fr. or drupe; endosp. little or none.

 Vitaceae: climbing shrubs often with tendrils opp. 1.; like preceding, but berry: C valv., often united above and falling as a

whole, G (2-8); endosp.

26

Elaeocarpaceae: woody pl. with simple stip. 1. and § 5—4-merous fls.; A ∞, G (2—∞) with ∞ ov. and 1 style, 2—∞-loc., rarely 1-loc.; caps., rarely drupe; sometimes aril; endosp.

Chlaenaceae: woody pl. with alt. stip. l. and g reg. fls.; K 5,

C 5-6, A 10- ∞ , G (3) each with 2 ov.; caps.; endosp.

Gonystilaceae: shrubs with alt. entire exstip. 1. and cymose panicles
of
 if reg. fls.; K 5—4, C 5—4, usu. divided, A ∞, anthers dithecous, G (5—3), each with 1 pend. ov.; berry; no endosp.

Tiliaceae: usu. woody pl. with alt. stip. 1. and & reg. fis.; K 5, C 5 or o, A & rarely to 10, free or in bundles, anthers dithecous,

 $G(2-\infty)$, each with $1-\infty$ ov., $2-\infty$ -loc.; endosp.

5. Malvaceae: herbs, shrubs, or trees with simple or lobed stip. I. and y usu. conspic. fis., sol., or in infis.; K 5, often with epicalyx, C 5, conv., A usu. ∞ in 2 whorls, united in a tube below, monothecous, with thorny pollen, G (5—∞), each with I—∞ ov.; styles as many or twice; caps. or schizocarp; endosp.

 Bombacaceae: woody pl. with entire or palmate stip. l. and often conspic. fls.; like last, but anthers with 1, 2 or more loc. and smooth pollen; G (2-5) with 2-0 ov., seeds sometimes en-

closed in hairs from pericarp; endosp. thin or o.

7. Sterculiaceae: trees, shrubs and herbs with alt. simple or cpd. stip. l. and complex infls. of \(\frac{1}{2} \) or \(\frac{2}{2} \) fls.; (K), C conv. or o, A in 2 whorls, the outer stds., the inner often branched, all \(\frac{1}{2} \) united; anthers 2-loc., often andro-gynophore; \(\frac{1}{2} \) usu. (5), antepet., each with 2-\(\frac{1}{2} \) ov.; usu. schizocarp; endosp.

Scytopetalaceae: woody pl. with alt. leathery l. and bunches or racemes of long-stalked fla.; K dish-like, C 3—7 valv., A ω, G (4—6), each with 2—6 pend. ov.; fr. woody or drupe, 1-

seeded.

27

E. Dilleniaceae: woody, sometimes climbing, rarely herbs, with usu. entire alt. evergr. 1., stip. or not, and usu. g reg. yellow or white fis.; K 3-∞, C 5-3, A ∞, rarely 10 or less, G ∞-1, each with 1-∞ ov.; fr. dehisc. or not; aril; endosp.

 Tamaricineae: G free on flat axis; endosp. starchy or none, C free, A in whorls, or if ∞ in bundles (fams. 10—12).

- 3. Fouquierineae: as last, but endosp. oily, and (C) (fam. 13).
- Cistineae: G free on flat or convex axis; endosp. starchy, C free, A ∞ not in bundles (fams. 14, 18).

- Eucryphiaceae: woody with evergr. opp. stip. 1. and sol. axillary

 y reg. white fis.; K, C 4, A ∞, G (5-18) each with ∞ pend.
 ov., becoming free on ripening; seed winged; endosp.
- 3. Ochnaceae: woody, or undershrubs with evergr. stip. l., usu. with # lat. nerves, and panicles of showy usu. yellow # reg. (rarely -|-) ffs., axis often enlarging after ffg.; K 4—10, C 5, rarely 4—10, A 5—10—∞, sometimes stds., G (2—5—10) with one style, often free below, with —1 erect or pend. ov.; endosp or o.

Caryocaraceae: woody with ternate evergr. stip. 1. and term. racemes of

g reg. fis.; K (5), C (5), A ∞, G (4-8-20) rarely (1-3) each loc. with 1 pend. ov.; schizocarp; endosp. thin or o.

5. Marcgraviaceae: woody, often climbing and epiph., with simple exstip. I. and racemes of ₹ reg. fls., the br. metam. into hollow nectaries; K 4.—5, C (4.—5), A 3.—6.—∞, G (5) or (2.—8.—∞) with ∞ ov. on originally parietal plac. afterwards meeting in centre; caps.; no endosp.

6. Quiinaceae: woody with shining evergr. stip. 1. and racemes or panicles of \$\vec{a}\$ of \$\vec{c}\$ erg. fls.; K, C 4—5, A 15—30, \$\vec{G}\$ (2—3) or (7), each with 2 axile ov.; berry, seeds felted.

7. Theaceae: woody with simple usu. alt. exstip. 1. and § reg. fis.; K 5-7, C 5-9, sometimes united below, A∞-5, sometimes in bundles, G (3-5) or (2-∞) with ∞-1 ov. in each on axile plac.; caps.; endosp. or o.

8. Guttiferae: woody, rarely herbs, with simple usu. opp. rarely stip. l., resin passages, and \(\varphi\) or \(\sigma\) ? reg. fls.; A ∞ —4, often partly stds. and united in groups, \(\overline{G}\) (3—5) or (1—15) with ∞—1 ov.; caps., berry, or drupe; no endosp.

Dipterocarpaceae: trees with alt. evergr. stip. 1., resin passages, and panicles of \underline{v} reg. fls.; K 5 (2, 3 or all lengthening to wings on the fr.), C 5 free or united, A ∞ or 15—10—5, \underline{G} (3—1) each

with ∞—2 ov.; fr. usu. 1-seeded indeh.; no endosp.

10. Elatinaceae: undershrubs or herbs, often water pl. with opp. or

whorled stip. I. and small \$\forall\$ reg. fis., axillary or in cymes, K, C 2-5, A 2-5 or 4-10, G (2-5) with \$\infty\$ axill. ov.; caps.; endosp. thin or o.

11. Frankeniaceae: undershrubs or herbs with small opp. exstip. 1. and term. or cymed § reg. 4—6-merous fls.; (K), C with ligule, A usu. 6, sometimes ∞, free or united below, G (4—2) with ∞ erect ov. on parietal plac.; caps.; endosp.

12. Tamaricaceae: ahrubs or herbs with small alt. exstip. l. and ÿ reg. 4—6-merous fls.; A as many or twice as many as C, or ∞ in groups, G (5—2) with ∞ ascending ov. on basal plac.; style divided; caps.; seed hairy; endosperm or none.

13. Fouquieriaceae: shrubs with decid. 1. and thorny midrib, and racemes or panicles of showy 7 reg. fls.; K 5, C (5), A 10—15, G (3), each with 4—6 ov.; seeds hairy or winged; endosp.

14. Cistacese: herbs and shrubs with usu. opp. 1. with glandular bairs and ethereal oil, and ∉ reg. fis.; K 5—3, C 5—3—o, A ∞, G (3—10) with ∞ or 2 ov. on parietal plac.; caps.; endosp.

15. Bixaceae: woody pl. with alt. simple l. and showy i reg. fis. in panicles; K, C 5, A ∞, G (2) each with ∞ ov. on parietal plac.; style r; capa.; endosp.

XXXIV

DICOTS. PARIETALES B; d; c

- Cochlospermineae: as last, but endosp. of kidney-shaped seed oily (fam. 16).
- Flacourtiineae: G free on convex axis, or in tubular axis
 rarely united at sides to G; endosp. oily (fams. 17—24).

- Papayineas: G free in tubular or bell-shaped axis; endosp. oily; latex (fam. 25).
- Loasineas: G sunk in and united to axis; endosp. oily, rarely none (fam. 26).
- Datiscineas: G sunk in and united to axis; endosp. thin, embryo oily; fis. in racemes (fam. 27).
- Begoniineae: as last, but no endosp.; fis. in dichasia or scorpiold cymes (fam. 28).

- 16. Cochlospermaceae: woody, usu. with lobed or cpd. l. and showy $\frac{1}{2}$ reg. or $\frac{1}{2}$ fis. in racemes or panicles; K, C₄-5, A ∞ , G (3-5) each with co ov. on parietal or almost central plac.; caps.; endosp.
- 17. Winteranaceae: woody pl. with alt. exstip. l. and cymose umbels of \(\text{reg. fls.}; \) K 4-5, C 4-5 or 0, A (20 or less), \underline{G} (2-5) with 2-∞ ov. on parietal plac.; berry; endosp.
- 18. Violaceae: herbs, or woody, with alt. stip. I. and y reg. or | fls.; K, C, A 5, G (3), each with 1-∞ ov. on parietal plac.; caps. or berry; endosp.
- 19. Flacourtiaceae: usu. woody pl. with alt. stip. simple 1., and y or s ? reg. fls.; K 2—15, C 15—0, A usu. ∞, G or semi-inf. (2— 10) usu. with co ov. on parietal plac.; berry or caps.; often aril;
- 20. Stachyuraceae: small shrubs with alt. l. and racemes of small \(\varphi \) or polyg. reg. fls.; K, C 4, A 8, G (4) with ∞ ov.; berry; aril; endosp.
- 21. Turneraceae: herbs, trees or shrubs with alt. l., stip. or not, and axillary or racemed or cymed & reg. fls. with tubular axis; K, C, A 5, G (3), each with 3-0 ov. on parietal plac.; style divided; caps.; aril; endosp.
- 22. Malesherbiaceae: herbs or undershrubs with alt. exstip. usu. very hairy l. and racemes or cymes of \$\forall \text{ reg. 5-merous fls. with tubular} axis and gynophore; A 5, concrescent with gynophore, G (3) with ∞ ov. on parietal plac.; caps.; no aril.
- 23. Passifleraceae: herbs or shrubs often climbing by tendrils with simple usu. palmately lobed 1., stip. or not, and fis. sol. or in racemes or cymes, reg., $\frac{1}{2}$ or $\frac{1}{6}$, with axis often \pm tubular ending in effigurations; K, C 5, rarely 3—8, A usu. 5 or 4—8, rarely ∞ , united to prolongation of axis, G (3-5) usu. with co ov. on parietal plac.; caps. or berry; usu. aril and endosp.
- 24. Achariaceae: herbs or undershrubs with simple or lobed 1. and single fls. or few in an axil, & ? reg., 3—5-merous; K, C, A 3—5, G as last; caps.; endosp.
- 25. Caricaceae: woody pl. with simple or cpd. exstip. l. and axillary infis. of 3? reg. fis. with hollow axis; K 5, C (5) in long tube in δ , short in θ ; A 5+5, G (3-5) with ∞ ov. on parietal plac.; berry; endosp.
- 26. Loasaceae: herbs, rarely shrubs, sometimes twining, with alt. or opp. exstip. I. and often stinging hairs, and y fls.; K 5 (rarely 4-7), C 5, rarely united, often boat-shaped, A ∞ , those before K often transformed to nectaries, G (3-7) each with 1- ∞ ov., usu. on parietal plac.; caps. sometimes spirally twisted; endosp.
- 27. Datiscaceae: herbs or shrubs with exstip. I. and racemes of small usu. & ? fis.; & K 3-9, C 0-4-9, A 4-25, V and ? P 3-8, G (3-8) with parietal plac. and ∞ ov.; caps.; endosp. slight.
- 48. Begoniaceae: herbs or undershrubs with alt. asymmetric stip. l. and dichasia or cymes of & 2 fis.; & K 2, rarely 5, C 2-6 or 0, A ∞ , ? P 5—2 or 3+3 or 8, G (3), rarely (4—5) with ∞ ov. on parietal plac. often united in middle; caps.; no endosp.

xxxvi DICOTS. PARIETALES-MYRTIFLORAE B; d; \(\xi \); \(\zeta \)

- Ancistrocladineae: G sunk in and united to axis, 1-loc. with 1 basal ov.; endosp. ruminate, starchy (fam. 29).
- 28. OPUNTIALES. Succulents, usu. without I., often thorny, with hemicyclic, heterochlam.,

 greg., or rarely +, fls.; K, C, A ∞, on tubular axis, and G (4—∞), 1-loc. with ∞ ov. on parietal plac.; berry-like fr. with ∞ seeds; endosp.

Fis. cyclic; G usu. sunk in hollow axis, and usu. united thereto (Orders 29, 30).

- 29, MYRTIFLORAE. Herbs or woody pl., with cyclic heterochlam., rarely apet. or + fls. with concave axis; A in 1 or 2 whorls, sometimes branched and in bundles, G (2—∞) usu. united to axis, rarely 1 free.
 - I. Thymelaeineae: woody pl. rarely herbs, with simple 1.; fls. with dish or tubular axis (at least in \$\frac{1}{2}\$ and \$\frac{1}{2}\$), reg. with (2—4) cpls. free of axis (fams. 1—5).

 Myrtineae: herbs or woody pl. with alt, or opp. l. and fls. with tubular axis and (2-∞) cpls. usu. united to axis: ov. with 1 integ. (fams. 6-17). 29. Ancistrocladaceae: lianes with lanc. l. and racemes or panicles of greg. fis.; K 5, C 5, slightly united below, A 5—10, \overline{G} (3), only 1 loc. with 1 basal ov.; nut; endosp.

28

1. Cactaceae:

29

- Geissolomataceae: shrub with opp. evergr. l. and sol. axillary & fls.;
 K 4, imbr., C o, A 4+4, G (4), each with 2 pend. ov.; 1 style;
 caps; endosp.
- Penaeaceae: shrubs with small opp. 1. and sol. axillary § reg. fis., K 4, valv., C o, A 4, G (4), each with 2-4 erect ov.; 1 style; caps.; no endosp.
- Oliniaceae: shrubs with opp. leathery l. and small v fls. in cymose umbels at ends of twigs; K 4—5, petaloid, C 4—5, smaller, A 4—5, anteposed, G (3—5) each with 2—3 axile ov.; I style; drupe; no endosp.
- 4. Thymelaeaceae: shrubs and trees, rarely herbs, with entire alt. or opp. exstip. I. and sol. or racemed or spiked \(\frac{1}{2} \) fis. with cup-like or tubular axis; \(K_5 \) 5—4, \(C_5 \) 5—4—o, \(A_5 \)—4 or 10—8, \(\frac{G}{2} \) 0 or 1, each with 1 pend. ov.; 1 style; endosp. or o.
- 5. Elaeagnaceae: woody with alt. or opp. entire l. and fls. as last, g or s with flat or cup-shaped axis; K 4, C usu. o, A 4 or 8, G 1 with 1 ascending ov.; nut; endosp. little or none.
- 6. Lythraceae: herbs and shrubs with simple entire usu. opp. stip. l. and racemes, panicles, or dichasia of \(\frac{3}{2}\), reg. or \(\frac{1}{2}\), 3—16- usu. 4—6-merous fis. with hollow or tubular axis; K valv., C sometimes o, A twice as many or I—∞, \(\frac{G}{2}\) (2—6), 2—6 rarely I-loc. each with ∞—2 ov.; caps.; no endosp.
- Sonneratiaceae: woody pl. with opp. exstip. l. and y or ♂ ? reg. fls. with bell-shaped axis; K 4—8, C 4—8 or o, A ∞, G (4—15) united to hollow axis, with 1 style, 4—15-loc. with ∞ ov.; caps. or berry-like fr.; no endosp.
- Punicaceae: woody pl. with entire l. and showy axillary y reg. fls.
 with top-shaped axis; K, C 5—7, A ∞, G (∞) in superposed
 whorls with ∞ ov. united to axis, I style; berry-like fr.; no
 endosp.
- 10. Rhizophoraceae: woody pl. usu. with opp. stip. l. and usu. g reg. fis., sol. or in cymose infis., hypog. to epig.; K 3—16, usu. 4—8, C as many or o, A 8—∞, G usu. (2—5), rarely 6, each with s—4—∞ pend. axile ov.; fr. usu. with s seed per loc.; sometimes vivinarous, endosp. or o.

xxxviii DICOTS. MYRTIFLORAE-UMBELLIFLORAE B; d; &

3. Hippuridineae: fls. epig. with 1 sta.; 1 cpl. with 1 ov. and no integ. (fam. 18).

4- Cynomoriineae: root paras. with epig. fis. with 1 sta., cpl. with 1 ov. with 1 integ. (fam. 19).

30. UMBELLIFLORAE. Fls. usu. in umbels, cyclic, heterochlam.; usu. with 1 whorl of sta., epig., 4—5-, rarely ∞-merous, ĕ reg.; G (5—1) or (∞) each with 1 (rarely 2) pend. ov. with 1 integ., rich endosp. 11. Nyssaceae: shrubs with alt. exstip. l. and small 2 or 3 ? fls. usu. with hollow axis, the 3 in racemes, the 2 sol., K 5 or more, C usu. 5, valv., or o, A twice as many, G usu. 1-loc. rarely 6—10-loc. with 1 ov. in each; drupe; endosp.

12. Alangiaceae: shrubs with alt. l. and umbels of \(\frac{1}{2} \) fis.; K (4—10), C 4—10, narrow, valv., A 4—10 or 2—4 times as many, \(\tilde{G} \) i—2-loc. with 1 pend. ov. in each; fr. drupaceous with 1 seed;

endosp.

13. Combretaceae: woody, often climbing, with opp. entire exstip. l. and racemes of \(\text{or } \text{d} \) or \(\text{d} \) \(\text{reg. fis.}; \(\text{K_LC}, 4-3, \text{rarely } 6-8 \) (C may be o), A 4-5-8-10, rarely \(\tilde{\text{O}}, \text{G} \) 1-loc. with 2-6 pend. ov.; fr. leathery or drupaceous, often winged; no endosp.

each with ∞ — 1 ov.; style 1; fr. various; no endosp.

15. Melastomaceae: herbs or woody pl. with opp. or whorled exstip. l. with often 3—9 equal nerves, and showy
reg. 3—∞-merous fls. with hollow axis; K=C, A twice as many, anthers usu. opening by pores, connective usu. with appendages, (G) usu.=K, free or united to axis, I style; seeds ∞ in caps. or berry; no endosp.

16. Onagraceae: usu. herbs with opp. or alt. exstip. l. and axillary or racemed a usu. reg. fls. with tubular axis; K 2-4, rarely more, C 2-4 or more or o, A usu. 4-8, G usu. (4), each with 1-20 ov.;

1 style; caps., nut, or berry; endosp. little or o.

17. Halorsgidaceae: herbs often of marsh or water, with inconspic.

reg. 4—1-merous g or 3 ? fls.; C often o, A twice or less, G (4),

rarely 1; fr. nut- or drupe-like; endosp.

18. Hippuridaceae: water pl. with whorled l. and inconspic. apet. fls.,

G I with I style and I pend. ov.

19. Cynomoriaceae: paras. with rhiz. and \$ or \$ \$ fls.; \$ with 1 epig. sta., \$ with 1 pend. ov.

30

Araliaceae: woody pl., rarely herbs, with usu. alt. often much divided 1., commonly stip., and oil passages, and usu. 5 (3-∞) merous fis. in heads, umbels, or spikes, often in cpd. infis.; K sometimes indistinct, A=C, G (∞-1); fr. berry- or drupe-like with ∞-1 stones; endosp.

2. Umbelliferae: herbs with tap root or rhiz., hollow stem, and altusu. much divided, sheathing exstip. 1., and usu. ? reg. small 5-merous fis, in umbels, simple or cpd.; K often indistinguishable, A=K, G (2) with two styles on swollen style base; schizocarp, the mericarps on a carpophore, each usu. with 5 ribs, often with vittae between; oily endosp.

3. Cornaceae: trees or shrubs with opp. or alt. usu. entire exstip. l., and umbels, panicles or heads of small, sometimes \$ 9, reg. 4—5—∞-merous fia.; A= or 2—4 times as many as C, G (4—1) with epig. disc and usu. 1 ov. each; fr. 1—4-loc. with 1—4 seeds.

xl DICOTS. ERICALES—PLUMBAGINALES A; B

Sympetalae (fl. usu. sympetalous)

- A. Fls. sometimes polypetalous; 2 or 1 whorls of sta.; usu. hypog., rarely epig. (Orders 1-3).
- 1. ERICALES. Woody pl. or herbs with simple 1. and § usn. reg. 5-4-merous fis.; C usu. united, A hypog. or epig., rarely united to pets. at base, obdipl., or whorl before C not developed, G 2-∞, usu. before C when equal in number, sup. to inf., ov. with I integ.

2. PRIMULALES. Fis. V or & V, reg., rarely 1., 5—(rarely 4—co)merous, usu. with 1 whorl of epipet. sta., rarely also 5 opp. K.; C usu. united, G apparently as many as C, sup. to inf., 1-loc. with ∞ -1 ov. on basal or free-central plac.

3. PLUMBAGINALES. Shrubs, undershrubs or herbs with simple i., often with water- or chalk-secreting glands and cpd. infl. of # fis.; C or (C), A in 1 whorl, G (5) with 5 stigs., 1-loc. with 1 ov.; endosp. starchy.

3. Fis. sympet. only; sta. sometimes ∞, usu. in 3—2 whorls; fi. usu.

hypog. (Order 4).

Sympetalae

Ŧ

c. Clethraceae: woody with alt. l. and racemes of

g reg., 5-merous obdipl. fls.; C free, A 10 hypog.,

G (3) each with

ov.; style long with 3 stigs.; caps. 3-valved; endosp.

 Lennoaceae: root paras. with ∞ ∉ reg. 5—∞-merous fls.; A=C, <u>G</u> (6—14) each with 2 ov. and false partition; drupe with 12—28 stones; endosp.

4. Ericaceae: usu. undershrubs or shrubs with alt. opp. or whorled usu. evergr. l. and single or racemed § 5—4-merous obdipl. fls.; C rarely free, inserted with sta. on disc, anther loc. often with projections, pollen in tetrads, (G) sup. or inf. with axile plac. each with 1—∞ ov., style 1 with capitate stig.; berry, drupe, caps.: endosp.

5. Epacridaceae: shrubs or undershrubs with stiff entire sess. alt. L. and usu. racemes of § reg. 5—4 merous fls.; (C), A=C, epipet. or at base of hypog. disc, thecae with common slit, G usu. (5) each with 1—∞ ov. on axile plac., style 1 with capitate stig.; caps. or drupe; endosp.

Diapensiaceae: undershrubs or woody herbs with # reg. fls.; K 5 or (5), C (5), A 10 obdipl., or 5, G (3) each with ∞ ov. on axile place, style 1; caps.; endosp.

2

Theophrastaceae: woody with alt. exstip. 1. often crowded at ends
of stem or branches, and ∀ or δ ? reg. rarely + fls.; K 5, C (5),
A 5+5 stds., G 1-loc. with ∞ ov. on free-central or basal plac.;
drupe with ∞ -2 seeds; endosp.

Myrsinaceae: woody with often evergr. entire alt. exstip. l., and g or d ? reg. fis.; K 5, C (5), A 5 rarely with 5 stds., G to G, I-loc. with so ov. on basal or free-central plac.; style I; drupe with I or few seeds; endosp.

Primulaceae: herbs with usu. alt. exstip. l. and # reg. rarely + fis.; K (5), C (5), A 5, epipet., anteposed, and rarely 5 stds., G rarely \(\frac{1}{2} \)-inf., r-loc. with \(\infty \) ov. on free-central plac.; caps.; endosp.

xlii DICOTS. EBENALES—CONTORTAE B; C

- EBENALES. Woody pl. with simple 1.; (C), A in 2-3 whorls, or in 1 by abortion, rarely ∞, G with axile plac. and several loc. with 1 or few ov. in each.
 - I. Sapotineae: G completely divided into loc., each with I ascending ov. with I integ. (fam. 1).
 - Diospyrineae: G or ½-inf. not chambered above; ov. with 2 integs. (fams. 2—4).

- C. Sympetaly the rule; sta. always in 1 whorl; union of cpls. sometimes small; usu. hypogyny (Order 5).
- CONTORTAE. Woody pl. or herbs with usu. opp. simple exstip.

 and usu. 5 (rarely 2—6)-merous fls.; usu. (C), rarely C or none, usu. conv., with as many or fewer sta. usu. epipet. at base of C, and G (2).
 - 1. Oleineae: sta. 2, ov. with 1 integ. (fam. 1).
 - 2. Gentianineae: A=C, G 1--2-loc. usu. with ∞ ov. on axile or parietal plac. with each 1 integ. (fams. 2--5).

1. Sapotaceae: woody with simple alt. 1., secretory passages, and usu. # As.: K 4-8 in two whorls, (C) as many in I whorl, or twice in 2, sometimes with lat. or dorsal appendages, A in 2 or 3 whorls, outer sometimes stds., (G) as many (or twice) as I whorl of sta., each with I basal or axile ov.; style I; berry; endosp. or o.

Ebenaceae: trees with entire alt. rarely opp. exstip. l., and usu. 3 ? fls., sol. or in few-fld. umbels, 3-more-merous; K persistent, C usu. conv., A as many, or 2-more times as many, free or united in bundles, G (2-16) each with 1-2 pend. ov.; berry with 1 or few seeds; endosp. often ruminate.

Symplocaceae: woody pl. with alt. exstip. 1. and § 5-merous fls.; C=or twice K, ± united, A epipet. in 1-3 whorls, G sometimes 1-inf. (5-2) each with 2-4 pend. ov.; style 1; drupe; endosp.

Styracaceae: woody pl. with simple alt. 1. with stellate or scaly hairs, and small or smallish & fls.; K, C (5-4), A 10-8 united at base or rarely into tube, G, rarely \(\frac{1}{2}\)-inf. (5-3) each with 1 or few ov., 3-5-loc. below, 1-loc. above; drupe, indeh. fr. or caps., with 1 or few seeds; endosp.

Oleaceae: woody, sometimes climbing, rarely herbs, with opp. or whorled simple or pinnate exstip. I., and cpd. infls. of \(\varphi \) or \(\varphi \) · reg. 2-6-merous fls.; C 4-5-6 or o, free or united, imbr. or valv., A 2 epipet. or hypog., G (2) each usu. with 2, rarely 1 or 4-8 axile ov.; caps., berry or drupe; endosp. or o.

Loganiaceae: woody, rarely herbs, with opp. or whorled often stip. L and cymose umbels of g or o g reg. fls.; K usu. imbr., C (4- $5-\infty$), valv., imbr., or conv., A=C or 1, G (2) rarely more with ∞ — 1 axile ov. and 1 style; caps.; endosp.

Gentianaceae: herbs, rarely shrubs with opp. entire exstip. I. and cymose infls. of usu. & reg. 4-5-merous fls.; K or (K), (C) usu. conv., A as many, G (2) usu. with ∞ ov. in 1-loc. ovary; caps.; endosp.

Apocynaceae: woody or herbs with simple usu. opp. entire l., and latex, and cymose infis. of \(\text{reg. 5-4-merous fis.; (C) usu. conv.,} \) A epipet., G (2) often only united by style; fr. various, endosperm thin or o.

Asclepiadaceae: herbs or shrubby, often climbing, some succulent, with opp. or whorled, rarely alt. exstip. l., and Freg. fls. sol. or in cymose umbels; K 5, C (5), usu. conv., sometimes with appendages forming a corona, A 5 usu. united below, usu. with appendages forming a corona, pollen usu. in pollinia with translators, G (2) enclosed in sta. tube, with ∞ rarely few or 1 pend. ov., united by style above; fr. s follicles, seeds usu. hairy; endosp.

DICOTS. TUBIFLORAE

D; a

- D. Fls. always sympetalous, with 1 whorl of sta., often ... with usu. 2 median cpls. fully united (Orders 6-10).
 - K, C hypogynous, with few exceptions (Orders 6, 7).
- 6. TUBIFLORAE. Usu. herbs, fls. typically with 4 isomerous whorls or usu. with oligomerous G, and if + also oligomerous A; sta. epipet., ov. with r integ.

I. Convolvulineae: l. usu. alt., fis. usu. reg.; cpls. with few or 2 ov. with micropyle downwards; fr. rarely 4 nutlets (fams. 1, 2).

- 2. Boraginineae: as last, but micropyle facing upwards; caps. or drupe, or 4 nutlets (fams. 3, 4).
- 3. Verbenineae: l. usu. opp. or whorled, fls. usu. . : cpls. with 2, rarely 1, ov.; fr. drupe or drupe-like, or 4 nutlets (fams. 5, 6).

- 4. Solanineae: fls. + or reg. usu. 5-merous; A 5-4-2, G rarely (5), usu. (2) with usu. ∞, rarely 2-1 ov.; fr. usu. caps., never splitting to base, rarely berry or drupe (fams. 7-17).
 - A. Fr. splitting into 5 or many mericarps (fam. 7).
 - B. Fr. 2-, rarely 5-00-loc., or 1-loc. (fams. 8-17).
 - 1. Vascular bundles bicollateral (fam. 8).
 - 2. Vascular bundles collateral (fams. 9-17).
 - i. G 2-loc. with so to few ov. (fams. 9-11).

Convolvulaceae: usu. herbs with alt. l., often twining, usu. with large # reg. 5—4-merous fls.; A epipet., G (2) rarely (3—5) each with 2 basal erect ov. on axile plac; caps.; endosp.

Polemoniaceae: usu. herbs with alt. or opp. exstip. l. and y usu. reg. 5-merous fls.; C usu. conv., G (3) rarely (2) or (5) each with co-r erect ov.; caps.; endosp.

 Hydrophyllaceae: herbs with alt. rarely opp. l. and scorpioid cymes of § reg. 5-merous fls.; A 5, G (2) each with ∞ -2 sessile or pend.

ov.; caps.; endosp.

4. Boraginaceae: herbs or woody pl., often roughly hairy, with usualt. simple l., and scorpioid cymes of a reg. 5 (rarely more)merous fis.; G (2) each with 2 ov., 2-loc., usu with false septum; fr. drupaceous or of 4 nutlets; endosp. or none.

5. Verbenaceae: herbs or woody pl. with usu. opp. or whorled entire or divided l. and cymose umbels of \(\frac{1}{2} \) usu. \(\frac{1}{2} \) -5—4 (rarely more)-merous fls.; (K), (C) often 2-lipped, A usu. 4 didynamous, or 2, \(\frac{1}{2} \) (2) rarely more, each with 2 ov., usu. 4-loc. by formation of secondary septa, style 1; drupe or schizocarp; usu. no endosp.

6. Labiatae: herbs or shrubs with decussate or whorled exstip. l. and cymose infls. often condensed in the axils into seeming whorls of y -1. 5-merous fls.; K (5), C usu. 2-lipped, A 4 didynamous or 2 with or without 2 stds., G (2) each with 2 erect ov., infolded between them; fr. of 4 nutlets; endosp. little or none.

 Nolanaceae: herbs or undershrubs with alt. 1. and sol. or racemed greg. fls.; K, C (5), A 5, G 5 with co ov., divided by long. or

transv. constrictions into 1-7-ovuled sections: endosp.

Solanaceae: herbs or shrubs with alt. I. and term. sol. or cymosely umbelled

 usu. reg. 5-merous fis.; A 5, G (a) obliquely placed, each with ∞ — 1 ov. on axile plac., style 1; berry or caps.; endosp.

 Scrophulariaceae: herbs or shrubs, rarely trees, with alt. opp. or whorled 1., and variously arranged fls., never term., ♥, = +, 5merous fls.; A usu. 4 or 2, G (2) median with each ∞ or few ov.

on axile plac., and 1 style; caps. or berry; endosp.

10. Bignoniaceae: woody pl. often climbing, with usu. opp. often cpd. l. and showy \$\displays + \displays - merous fis., often in cpd. infis.; A 4 or 2, sometimes with 3—1 stds., \$\overline{\Omega}\$ (2) median with \$\infty\$ ov., 2- or 1-loc., style 1; caps. or fleshy fr.; no endosp.

xlvi DICOTS. TUBIFLORAE—RUBIALES D; a; b; a

ii. G 1-loc. with ± parietal plac. and ∞ ov. (fams. 12—15).

- iii. G rarely 2-loc., usu. 1-loc. with basal central placand ∞ ov. (fam. 16).
- iv. G 2- or 1-loc., in each 1 pend. ov., or 1 pend. ov. only (fam. 17).
- g. Acanthineas: fls. usu. +, typically 5-merous; A 4 or 2, G (2) with usu. @ ov.; caps. loculicidal to very base (fam. 18).
- Myoporineae: woody with alt. or opp. l. and fls. reg. or 4, 5-merous; G (2) later 4-loc., each with 2-4-∞ ov., or (2-∞) each with 1 pend. ov. with micropyle upwards; drupe; endosp. thin or none (fam. 19).
- 7. Phrymineas: herba, fls. +; G 1 with 1 orthotr. ascending ov. (fam. 20).
- PLANTAGINALES. Usu. herbs, rarely shrubby, with usu. alt.
 1; fls. § or & ?, reg., 4-merous; K (4), C (4), membranous, A 4, epipet., G (2) or 1, 4—1-loc. with few or 1 anatr. ov.; caps. or nut; endosp.
 - b. P spigynous (Orders 8-10).
 - a. Sta. free (Order 8).
- 8. RUBIALES. Woody pl. or herbs with opp. usu. simple l. and usu. reg. 5—4-merous fis.; G 1-(or more)-loc., each with so—1 anatr. ov.
- A. Sta. = C segments (fams. 1-3).

- 11. Pedaliaceae: herbs with glandular hairs and opp. 1. (sometimes alt. above) and axillary or racemed \(\frac{1}{2} \cdot \c
- 12. Martyniaceae: as last, but anther thecae spurred; G with 2 bilobed parietal plac.; caps.; racemes; thin endosp.
- 13. Orobanchaceae: paras. herbs with scaly l. and term. or racemed # + 5-merous fls.; C 2-lipped, A 4 didynamous, G (2), rarely (3), each with 2 parietal plac. sometimes united in middle, and ∞ ov., 1 style; caps.; endosp.
- 14. Gesneriaceae: herbs or woody pl. with opp. simple 1. and showy sol. or cymosely umbelled \$\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}\cdot
- 15. Columelliaceae: woody pl. with opp. entire l. and cymose umbels of a nearly reg. 5—8-merous fls.; A 2, G (2) with ∞ ov. on 2 parietal bilobed plac.; caps. 4-valved; endosp.
- Lentibulariaceae: herbs, usu. of water or damp ground, with \$ + 5-merous fls.; C 2-lipped, A usu. 2, G (2) usu. 1-loc. with basal free plac. and ∞ ov.; caps. 2—4-valved, ∞ or 1-seeded; no endosp.
- 17. Globulariaceae: herbs with rad. 1. and spherical heads or spikes of \$5-merous + fls.; A 4 or 2, G(2) 1-loc. each with 1 ov., or 1 ov. only, 1 style; 1-seeded nut; endosp.
- 18. Acanthaceae: herbs or shrubs with opp. I. and spikes, racemes or cymose umbels of § +5-merous fls.; K free or united, C reg. or +, A 4 or 2, sometimes with 1-3 stds., G (2) median, each with ∞-2 ov.; caps. loculicidal to very base; seeds usu. with no endosp. and with jaculators.
- 10. Myoporaceae:
- 20. Phrymaceae:

7

I. Plantaginaceae:

8

I. Rubiaceae: herbs or woody pl. with decussate entire l. and interpetiolar stips. sometimes = l., and usu. § reg. fls. in cymes often condensed to heads, 5—4 (rarely more)-merous; K usu. open, C valv. or conv., G (2) each with 1—20 ov., style 1; fr. various; andogo. or o.

xlviii DICOTS. RUBIALES—CAMPANULATAE D; b; α; β

B. Sta. fewer than C segments, \$\overline{G}\$ always with only 1 fertile loc. and 1 pend. ov. (fams. 4, 5).

β. Sta. close together or partly united (Orders 9, 10).

9. CUCURBITALES. Fls. typically 5-merous, usu. 3 ? reg., with cup-like axis; A 5 free, at edge of axis, or each 2 united, or all 5 in a central synandrium, G usu. (3), 3-loc. usu. with ∞ ov. and usu. (orked sties: fr. berry-like, no endosp.

usu. forked stigs.; fr. berry-like, no endosp.

10. CAMPANULATAE. Usu. herbs, rarely woody, with typically 5-merous fis. with 1 whorl of sta. and usu. fewer cpls.; anthers with 2-loc. thecae, often united, G or G with several loc. and ∞—1 ov. in each, or 1-loc. with 1 ov.
